In the Postgres Pro parser, life is a bit more complicated. There are several different classes of tokens ranging from those that can never be used as an identifier to those that have absolutely no special status in the parser, but are considered ordinary identifiers. (The latter is usually the case for functions specified by SQL.) Even reserved key words are not completely reserved in Postgres Pro, but can be used as column labels (for example, `SELECT 55 AS CHECK`, even though `CHECK` is a reserved key word).

In [Table C.1](#) in the column for Postgres Pro we classify as “non-reserved” those key words that are explicitly known to the parser but are allowed as column or table names. Some key words that are otherwise non-reserved cannot be used as function or data type names and are marked accordingly. (Most of these words represent built-in functions or data types with special syntax. The function or type is still available but it cannot be redefined by the user.) Labeled “reserved” are those tokens that are not allowed as column or table names. Some reserved key words are allowable as names for functions or data types; this is also shown in the table. If not so marked, a reserved key word is only allowed as a column label. A blank entry in this column means that the word is treated as an ordinary identifier by Postgres Pro.

Furthermore, while most key words can be used as “bare” column labels without writing `AS` before them (as described in [Section 7.3.2](#)), there are a few that require a leading `AS` to avoid ambiguity. These are marked in the table as “requires `AS`”.

As a general rule, if you get spurious parser errors for commands that use any of the listed key words as an identifier, you should try quoting the identifier to see if the problem goes away.

It is important to understand before studying [Table C.1](#) that the fact that a key word is not reserved in Postgres Pro does not mean that the feature related to the word is not implemented. Conversely, the presence of a key word does not indicate the existence of a feature.

Table C.1. SQL Key Words

Appendix D. SQL Conformance

This section attempts to outline to what extent Postgres Pro conforms to the current SQL standard. The following information is not a full statement of conformance, but it presents the main topics in as much detail as is both reasonable and useful for users.

The formal name of the SQL standard is ISO/IEC 9075 “Database Language SQL”. A revised version of the standard is released from time to time; the most recent update appearing in 2023. The 2023 version is referred to as ISO/IEC 9075:2023, or simply as SQL:2023. The versions prior to that were SQL:2016, SQL:2011, SQL:2008, SQL:2006, SQL:2003, SQL:1999, and SQL-92. Each version replaces the previous one, so claims of conformance to earlier versions have no official merit. Postgres Pro development aims for conformance with the latest official version of the standard where such conformance does not contradict traditional features or common sense. Many of the features required by the SQL standard are supported, though sometimes with slightly differing syntax or function. Further moves towards conformance can be expected over time.

SQL-92 defined three feature sets for conformance: Entry, Intermediate, and Full. Most database management systems claiming SQL standard conformance were conforming at only the Entry level, since the entire set of features in the Intermediate and Full levels was either too voluminous or in conflict with legacy behaviors.

Starting with SQL:1999, the SQL standard defines a large set of individual features rather than the ineffectively broad three levels found in SQL-92. A large subset of these features represents the “Core” features, which every conforming SQL implementation must supply. The rest of the features are purely optional.

The standard is split into a number of parts, each also known by a shorthand name:

- ISO/IEC 9075-1 Framework (SQL/Framework)
- ISO/IEC 9075-2 Foundation (SQL/Foundation)
- ISO/IEC 9075-3 Call Level Interface (SQL/CLI)
- ISO/IEC 9075-4 Persistent Stored Modules (SQL/PSM)
- ISO/IEC 9075-9 Management of External Data (SQL/MED)
- ISO/IEC 9075-10 Object Language Bindings (SQL/OLB)
- ISO/IEC 9075-11 Information and Definition Schemas (SQL/Schemata)
- ISO/IEC 9075-13 Routines and Types using the Java Language (SQL/JRT)
- ISO/IEC 9075-14 XML-related specifications (SQL/XML)
- ISO/IEC 9075-15 Multi-dimensional arrays (SQL/MDA)
- ISO/IEC 9075-16 Property Graph Queries (SQL/PGQ)

Note that some part numbers are not (or no longer) used.

The Postgres Pro core covers parts 1, 2, 9, 11, and 14. Part 3 is covered by the ODBC driver, and part 13 is covered by the PL/Java plug-in, but exact conformance is currently not being verified for these components. There are currently no implementations of parts 4, 10, 15, and 16 for Postgres Pro.

Postgres Pro supports most of the major features of SQL:2023. Out of 177 mandatory features required for full Core conformance, Postgres Pro conforms to at least 170. In addition, there is a long list of

supported optional features. It might be worth noting that at the time of writing, no current version of any database management system claims full conformance to Core SQL:2023.

In the following two sections, we provide a list of those features that Postgres Pro supports, followed by a list of the features defined in SQL:2023 which are not yet supported in Postgres Pro. Both of these lists are approximate: There might be minor details that are nonconforming for a feature that is listed as supported, and large parts of an unsupported feature might in fact be implemented. The main body of the documentation always contains the most accurate information about what does and does not work.

Note

Feature codes containing a hyphen are subfeatures. Therefore, if a particular subfeature is not supported, the main feature is listed as unsupported even if some other subfeatures are supported.

D.1. Supported Features

Identifier	Core?	Description	Comment

F863		Nested OFFSET in query expression	
F864		Top-level OFFSET in views	
F865		Dynamic offset row count in OFFSET	
F867		FETCH FIRST clause: WITH TIES option	
F868		ORDER BY in grouped table	
F869		SQL implementation info population	
S071		SQL paths in function and type name resolution	
S090		Minimal array support	
S092		Arrays of user-defined types	
S095		Array constructors by query	
S096		Optional array bounds	
S098		ARRAY_AGG	
S099		Array expressions	
S111		ONLY in query expressions	
S201		SQL-invoked routines on arrays	
S203		Array parameters	
S204		Array as result type of functions	
S211		User-defined cast functions	
S301		Enhanced UNNEST	
S404		TRIM_ARRAY	
T031		BOOLEAN data type	
T054		GREATEST and LEAST	different null handling
T055		String padding functions	
T056		Multi-character TRIM functions	
T061		UCS support	
T071		BIGINT data type	
T081		Optional string types maximum length	
T121		WITH (excluding RECURSIVE) in query expression	
T122		WITH (excluding RECURSIVE) in subquery	
T131		Recursive query	

Identifier	Core?	Description	Comment
T132		Recursive query in subquery	
T133		Enhanced cycle mark values	
T141		SIMILAR predicate	
T151		DISTINCT predicate	
T152		DISTINCT predicate with negation	
T171		LIKE clause in table definition	
T172		AS subquery clause in table definition	
T173		Extended LIKE clause in table definition	
T174		Identity columns	
T177		Sequence generator support: simple restart option	
T178		Identity columns: simple restart option	
T191		Referential action RESTRICT	
T201		Comparable data types for referential constraints	
T212		Enhanced trigger capability	
T213		INSTEAD OF triggers	
T214		BEFORE triggers	
T215		AFTER triggers	
T216		Ability to require true search condition before trigger is invoked	
T217		TRIGGER privilege	
T241		START TRANSACTION statement	
T261		Chained transactions	
T271		Savepoints	
T281		SELECT privilege with column granularity	
T285		Enhanced derived column names	
T312		OVERLAY function	
T321-01	Core	User-defined functions with no overloading	
T321-02	Core	User-defined stored procedures with no overloading	
T321-03	Core	Function invocation	
T321-04	Core	CALL statement	
T321-05	Core	RETURN statement	
T321-06	Core	ROUTINES view	
T321-07	Core	PARAMETERS view	
T323		Explicit security for external routines	
T325		Qualified SQL parameter references	
T331		Basic roles	
T332		Extended roles	
T341		Overloading of SQL-invoked functions and SQL-invoked procedures	
T351		Bracketed comments	
T431		Extended grouping capabilities	

Identifier	Core?	Description	Comment
T432		Nested and concatenated GROUPING SETS	
T433		Multi-argument GROUPING function	
T434		GROUP BY DISTINCT	
T441		ABS and MOD functions	
T461		Symmetric BETWEEN predicate	
T491		LATERAL derived table	
T501		Enhanced EXISTS predicate	
T521		Named arguments in CALL statement	
T523		Default values for INOUT parameters of SQL-invoked procedures	
T524		Named arguments in routine invocations other than a CALL statement	
T525		Default values for parameters of SQL-invoked functions	
T551		Optional key words for default syntax	
T581		Regular expression substring function	
T591		UNIQUE constraints of possibly null columns	
T611		Elementary OLAP operations	
T612		Advanced OLAP operations	
T613		Sampling	
T614		NTILE function	
T615		LEAD and LAG functions	
T617		FIRST_VALUE and LAST_VALUE functions	
T620		WINDOW clause: GROUPS option	
T621		Enhanced numeric functions	
T622		Trigonometric functions	
T623		General logarithm functions	
T624		Common logarithm functions	
T626		ANY_VALUE	
T627		Window framed COUNT DISTINCT	
T631	Core	IN predicate with one list element	
T651		SQL-schema statements in SQL routines	
T653		SQL-schema statements in external routines	
T655		Cyclically dependent routines	
T661		Non-decimal integer literals	
T662		Underscores in numeric literals	
T670		Schema and data statement mixing	
T803		String-based JSON	
T811		Basic SQL/JSON constructor functions	
T812		SQL/JSON: JSON_OBJECTAGG	
T813		SQL/JSON: JSON_ARRAYAGG with ORDER BY	
T814		Colon in JSON_OBJECT or JSON_OBJECTAGG	

Identifier	Core?	Description	Comment
T821		Basic SQL/JSON query operators	
T822		SQL/JSON: IS JSON WITH UNIQUE KEYS predicate	
T823		SQL/JSON: PASSING clause	
T824		JSON_TABLE: specific PLAN clause	
T825		SQL/JSON: ON EMPTY and ON ERROR clauses	
T826		General value expression in ON ERROR or ON EMPTY clauses	
T827		JSON_TABLE: sibling NESTED COLUMNS clauses	
T828		JSON_QUERY	
T829		JSON_QUERY: array wrapper options	
T830		Enforcing unique keys in SQL/JSON constructor functions	
T831		SQL/JSON path language: strict mode	
T832		SQL/JSON path language: item method	
T833		SQL/JSON path language: multiple subscripts	
T834		SQL/JSON path language: wildcard member accessor	
T835		SQL/JSON path language: filter expressions	
T836		SQL/JSON path language: starts with predicate	
T837		SQL/JSON path language: regex_like predicate	
T838		JSON_TABLE: PLAN DEFAULT clause	
T840		Hex integer literals in SQL/JSON path language	
T851		SQL/JSON: optional keywords for default syntax	
T879		JSON in equality operations	with jsonb
T880		JSON in grouping operations	with jsonb
X010		XML type	
X011		Arrays of XML type	
X014		Attributes of XML type	
X016		Persistent XML values	
X020		XMLConcat	
X031		XMLElement	
X032		XMLForest	
X034		XMLAgg	
X035		XMLAgg: ORDER BY option	
X036		XMLComment	
X037		XMLPI	
X040		Basic table mapping	
X041		Basic table mapping: null absent	
X042		Basic table mapping: null as nil	
X043		Basic table mapping: table as forest	
X044		Basic table mapping: table as element	
X045		Basic table mapping: with target namespace	

Identifier	Core?	Description	Comment
X046		Basic table mapping: data mapping	
X047		Basic table mapping: metadata mapping	
X048		Basic table mapping: base64 encoding of binary strings	
X049		Basic table mapping: hex encoding of binary strings	
X050		Advanced table mapping	
X051		Advanced table mapping: null absent	
X052		Advanced table mapping: null as nil	
X053		Advanced table mapping: table as forest	
X054		Advanced table mapping: table as element	
X055		Advanced table mapping: with target namespace	
X056		Advanced table mapping: data mapping	
X057		Advanced table mapping: metadata mapping	
X058		Advanced table mapping: base64 encoding of binary strings	
X059		Advanced table mapping: hex encoding of binary strings	
X060		XMLParse: character string input and CONTENT option	
X061		XMLParse: character string input and DOCUMENT option	
X069		XMLSerialize: INDENT	
X070		XMLSerialize: character string serialization and CONTENT option	
X071		XMLSerialize: character string serialization and DOCUMENT option	
X072		XMLSerialize: character string serialization	
X090		XML document predicate	
X120		XML parameters in SQL routines	
X121		XML parameters in external routines	
X221		XML passing mechanism BY VALUE	
X301		XMLTable: derived column list option	
X302		XMLTable: ordinality column option	
X303		XMLTable: column default option	
X304		XMLTable: passing a context item	must be XML DOCUMENT
X400		Name and identifier mapping	
X410		Alter column data type: XML type	

D.2. Unsupported Features

The following features defined in SQL:2023 are not implemented in this release of Postgres Pro. In a few cases, equivalent functionality is available.

Identifier	Core?	Description	Comment
B011		Embedded Ada	
B013		Embedded COBOL	

Identifier	Core?	Description	Comment
B014		Embedded Fortran	
B015		Embedded MUMPS	
B016		Embedded Pascal	
B017		Embedded PL/I	
B030		Enhanced dynamic SQL	
B031		Basic dynamic SQL	
B032		Extended dynamic SQL	
B033		Untyped SQL-invoked function arguments	
B034		Dynamic specification of cursor attributes	
B035		Non-extended descriptor names	
B036		Describe input statement	
B041		Extensions to embedded SQL exception declarations	
B051		Enhanced execution rights	
B111		Module language Ada	
B112		Module language C	
B113		Module language COBOL	
B114		Module language Fortran	
B115		Module language MUMPS	
B116		Module language Pascal	
B117		Module language PL/I	
B121		Routine language Ada	
B122		Routine language C	
B123		Routine language COBOL	
B124		Routine language Fortran	
B125		Routine language MUMPS	
B126		Routine language Pascal	
B127		Routine language PL/I	
B200		Polymorphic table functions	
B201		More than one PTF generic table parameter	
B202		PTF copartitioning	
B203		More than one copartition specification	
B204		PRUNE WHEN EMPTY	
B205		Pass-through columns	
B206		PTF descriptor parameters	
B207		Cross products of partitionings	
B208		PTF component procedure interface	
B209		PTF extended names	
B211		Module language Ada: VARCHAR and NUMERIC support	
B221		Routine language Ada: VARCHAR and NUMERIC support	

Identifier	Core?	Description	Comment
F054		TIMESTAMP in DATE type precedence list	
F120		Get diagnostics statement	
F121		Basic diagnostics management	
F122		Enhanced diagnostics management	
F123		All diagnostics	
F124		SET TRANSACTION statement: DIAGNOSTICS SIZE clause	
F263		Comma-separated predicates in simple CASE expression	
F291		UNIQUE predicate	
F301		CORRESPONDING in query expressions	
F403		Partitioned join tables	
F451		Character set definition	
F461		Named character sets	
F492		Optional table constraint enforcement	
F521		Assertions	
F671		Subqueries in CHECK constraints	intentionally omitted
F673		Reads SQL-data routine invocations in CHECK constraints	
F693		SQL-session and client module collations	
F695		Translation support	
F696		Additional translation documentation	
F721		Deferrable constraints	foreign and unique keys only
F741		Referential MATCH types	no partial match yet
F812		Basic flagging	
F813		Extended flagging	
F821		Local table references	
F831		Full cursor update	
F832		Updatable scrollable cursors	
F833		Updatable ordered cursors	
F841		LIKE_REGEX predicate	consider regexp_like()
F842		OCCURRENCES_REGEX function	consider regexp_matches()
F843		POSITION_REGEX function	consider regexp_instr()
F844		SUBSTRING_REGEX function	consider regexp_substr()
F845		TRANSLATE_REGEX function	consider regexp_replace()
F846		Octet support in regular expression operators	
F847		Non-constant regular expressions	
F866		FETCH FIRST clause: PERCENT option	
R010		Row pattern recognition: FROM clause	

Identifier	Core?	Description	Comment
R020		Row pattern recognition: WINDOW clause	
R030		Row pattern recognition: full aggregate support	
S011	Core	Distinct data types	
S011-01	Core	USER_DEFINED_TYPES view	
S023		Basic structured types	
S024		Enhanced structured types	
S025		Final structured types	
S026		Self-referencing structured types	
S027		Create method by specific method name	
S028		Permutable UDT options list	
S041		Basic reference types	
S043		Enhanced reference types	
S051		Create table of type	partially supported
S081		Subtables	
S091		Basic array support	partially supported
S093		Arrays of distinct types	
S094		Arrays of reference types	
S097		Array element assignment	
S151		Type predicate	see pg_typeof()
S161		Subtype treatment	
S162		Subtype treatment for references	
S202		SQL-invoked routines on multisets	
S231		Structured type locators	
S232		Array locators	
S233		Multiset locators	
S241		Transform functions	
S242		Alter transform statement	
S251		User-defined orderings	
S261		Specific type method	
S271		Basic multiset support	
S272		Multisets of user-defined types	
S274		Multisets of reference types	
S275		Advanced multiset support	
S281		Nested collection types	
S291		Unique constraint on entire row	
S401		Distinct types based on array types	
S402		Distinct types based on multiset types	
S403		ARRAY_MAX_CARDINALITY	
T011		Timestamp in Information Schema	
T021		BINARY and VARBINARY data types	

Identifier	Core?	Description	Comment
T022		Advanced support for BINARY and VARBINARY data types	
T023		Compound binary literals	
T024		Spaces in binary literals	
T039		CLOB locator: non-holdable	
T040		Concatenation of CLOBs	
T041		Basic LOB data type support	
T042		Extended LOB data type support	
T043		Multiplier T	
T044		Multiplier P	
T045		BLOB data type	
T046		CLOB data type	
T047		POSITION, OCTET_LENGTH, TRIM, and SUBSTRING for BLOBs	
T048		Concatenation of BLOBs	
T049		BLOB locator: non-holdable	
T050		POSITION, CHAR_LENGTH, OCTET_LENGTH, LOWER, TRIM, UPPER, and SUBSTRING for CLOBs	
T051		Row types	
T053		Explicit aliases for all-fields reference	
T062		Character length units	
T076		DECFLOAT data type	
T101		Enhanced nullability determination	
T111		Updatable joins, unions, and columns	
T175		Generated columns	mostly supported
T176		Sequence generator support	supported except for NEXT VALUE FOR
T180		System-versioned tables	
T181		Application-time period tables	
T200		Trigger DDL	similar but not fully compatible
T211		Basic trigger capability	
T218		Multiple triggers for the same event executed in the order created	intentionally omitted
T231		Sensitive cursors	
T251		SET TRANSACTION statement: LOCAL option	
T262		Multiple server transactions	
T272		Enhanced savepoint management	
T301		Functional dependencies	partially supported
T321	Core	Basic SQL-invoked routines	partially supported
T322		Declared data type attributes	
T324		Explicit security for SQL routines	

Identifier	Core?	Description	Comment
T326		Table functions	
T471		Result sets return value	
T472		DESCRIBE CURSOR	
T495		Combined data change and retrieval	different syntax
T502		Period predicates	
T511		Transaction counts	
T522		Default values for IN parameters of SQL-invoked procedures	supported except DE-FAULT key word in invocation
T561		Holdable locators	
T571		Array-returning external SQL-invoked functions	
T572		Multiset-returning external SQL-invoked functions	
T601		Local cursor references	
T616		Null treatment option for LEAD and LAG functions	
T618		NTH_VALUE function	function exists, but some options missing
T619		Nested window functions	
T625		LISTAGG	
T641		Multiple column assignment	only some syntax variants supported
T652		SQL-dynamic statements in SQL routines	
T654		SQL-dynamic statements in external routines	
T801		JSON data type	
T802		Enhanced JSON data type	
T839		Formatted cast of datetimes to/from character strings	
T860		SQL/JSON simplified accessor: column reference only	
T861		SQL/JSON simplified accessor: case-sensitive JSON member accessor	
T862		SQL/JSON simplified accessor: wildcard member accessor	
T863		SQL/JSON simplified accessor: single-quoted string literal as member accessor	
T864		SQL/JSON simplified accessor	
T865		SQL/JSON item method: bigint()	
T866		SQL/JSON item method: boolean()	
T867		SQL/JSON item method: date()	
T868		SQL/JSON item method: decimal()	
T869		SQL/JSON item method: decimal() with precision and scale	
T870		SQL/JSON item method: integer()	
T871		SQL/JSON item method: number()	
T872		SQL/JSON item method: string()	
T873		SQL/JSON item method: time()	

Identifier	Core?	Description	Comment
T874		SQL/JSON item method: time_tz()	
T875		SQL/JSON item method: time precision	
T876		SQL/JSON item method: timestamp()	
T877		SQL/JSON item method: timestamp_tz()	
T878		SQL/JSON item method: timestamp precision	
T881		JSON in ordering operations	with jsonb, partially supported
T882		JSON in multiset element grouping operations	
M001		Datalinks	
M002		Datalinks via SQL/CLI	
M003		Datalinks via Embedded SQL	
M004		Foreign data support	partially supported
M005		Foreign schema support	
M006		GetSQLString routine	
M007		TransmitRequest	
M009		GetOpts and GetStatistics routines	
M010		Foreign-data wrapper support	different API
M011		Datalinks via Ada	
M012		Datalinks via C	
M013		Datalinks via COBOL	
M014		Datalinks via Fortran	
M015		Datalinks via M	
M016		Datalinks via Pascal	
M017		Datalinks via PL/I	
M018		Foreign-data wrapper interface routines in Ada	
M019		Foreign-data wrapper interface routines in C	different API
M020		Foreign-data wrapper interface routines in COBOL	
M021		Foreign-data wrapper interface routines in Fortran	
M022		Foreign-data wrapper interface routines in MUMPS	
M023		Foreign-data wrapper interface routines in Pascal	
M024		Foreign-data wrapper interface routines in PL/I	
M030		SQL-server foreign data support	
M031		Foreign-data wrapper general routines	
X012		Multisets of XML type	
X013		Distinct types of XML type	
X015		Fields of XML type	
X025		XMLCast	
X030		XMLDocument	
X038		XMLText	
X065		XMLParse: binary string input and CONTENT option	
X066		XMLParse: binary string input and DOCUMENT option	

Identifier	Core?	Description	Comment
X068		XMLSerialize: BOM	
X073		XMLSerialize: binary string serialization and CONTENT option	
X074		XMLSerialize: binary string serialization and DOCUMENT option	
X075		XMLSerialize: binary string serialization	
X076		XMLSerialize: VERSION	
X077		XMLSerialize: explicit ENCODING option	
X078		XMLSerialize: explicit XML declaration	
X080		Namespaces in XML publishing	
X081		Query-level XML namespace declarations	
X082		XML namespace declarations in DML	
X083		XML namespace declarations in DDL	
X084		XML namespace declarations in compound statements	
X085		Predefined namespace prefixes	
X086		XML namespace declarations in XMLTable	
X091		XML content predicate	
X096		XMLExists	XPath 1.0 only
X100		Host language support for XML: CONTENT option	
X101		Host language support for XML: DOCUMENT option	
X110		Host language support for XML: VARCHAR mapping	
X111		Host language support for XML: CLOB mapping	
X112		Host language support for XML: BLOB mapping	
X113		Host language support for XML: STRIP WHITESPACE option	
X114		Host language support for XML: PRESERVE WHITESPACE option	
X131		Query-level XMLBINARY clause	
X132		XMLBINARY clause in DML	
X133		XMLBINARY clause in DDL	
X134		XMLBINARY clause in compound statements	
X135		XMLBINARY clause in subqueries	
X141		IS VALID predicate: data-driven case	
X142		IS VALID predicate: ACCORDING TO clause	
X143		IS VALID predicate: ELEMENT clause	
X144		IS VALID predicate: schema location	
X145		IS VALID predicate outside check constraints	
X151		IS VALID predicate: with DOCUMENT option	
X152		IS VALID predicate: with CONTENT option	
X153		IS VALID predicate: with SEQUENCE option	
X155		IS VALID predicate: NAMESPACE without ELEMENT clause	

Identifier	Core?	Description	Comment
X157		IS VALID predicate: NO NAMESPACE with ELEMENT clause	
X160		Basic Information Schema for registered XML schemas	
X161		Advanced Information Schema for registered XML schemas	
X170		XML null handling options	
X171		NIL ON NO CONTENT option	
X181		XML(DOCUMENT(UNTYPED)) type	
X182		XML(DOCUMENT(ANY)) type	
X190		XML(SEQUENCE) type

X284		XMLValidate: NAMESPACE without ELEMENT clause	
X286		XMLValidate: NO NAMESPACE with ELEMENT clause	
X300		XMLTable	XPath 1.0 only
X305		XMLTable: initializing an XQuery variable	

D.3. XML Limits and Conformance to SQL/XML

Significant revisions to the XML-related specifications in ISO/IEC 9075-14 (SQL/XML) were introduced with SQL:2006. Postgres Pro's implementation of the XML data type and related functions largely follows the earlier 2003 edition, with some borrowing from later editions. In particular:

- Where the current standard provides a family of XML data types to hold “document” or “content” in untyped or XML Schema-typed variants, and a type `XML(SEQUENCE)` to hold arbitrary pieces of XML content, Postgres Pro provides the single `xml` type, which can hold “document” or “content”. There is no equivalent of the standard's “sequence” type.
- Postgres Pro provides two functions introduced in SQL:2006, but in variants that use the XPath 1.0 language, rather than XML Query as specified for them in the standard.

This section presents some of the resulting differences you may encounter.

D.3.1. Queries Are Restricted to XPath 1.0

The Postgres Pro-specific functions `xpath()` and `xpath_exists()` query XML documents using the XPath language. Postgres Pro also provides XPath-only variants of the standard functions `xmlexists` and `xmltable`, which officially use the XQuery language. For all of these functions, Postgres Pro relies on the `libxml2` library, which provides only XPath 1.0.

There is a strong connection between the XQuery language and XPath versions 2.0 and later: any expression that is syntactically valid and executes successfully in both produces the same result (with a minor exception for expressions containing numeric character references or predefined entity references, which XQuery replaces with the corresponding character while XPath leaves them alone). But there is no such connection between these languages and XPath 1.0; it was an earlier language and differs in many respects.

There are two categories of limitation to keep in mind: the restriction from XQuery to XPath for the functions specified in the SQL standard, and the restriction of XPath to version 1.0 for both the standard and the Postgres Pro-specific functions.

D.3.1.1. Restriction of XQuery to XPath

Features of XQuery beyond those of XPath include:

- XQuery expressions can construct and return new XML nodes, in addition to all possible XPath values. XPath can create and return values of the atomic types (numbers, strings, and so on) but can only return XML nodes that were already present in documents supplied as input to the expression.
- XQuery has control constructs for iteration, sorting, and grouping.
- XQuery allows declaration and use of local functions.

Recent XPath versions begin to offer capabilities overlapping with these (such as functional-style `for-each` and `sort`, anonymous functions, and `parse-xml` to create a node from a string), but such features were not available before XPath 3.0.

D.3.1.2. Restriction of XPath to 1.0

For developers familiar with XQuery and XPath 2.0 or later, XPath 1.0 presents a number of differences to contend with:

- The fundamental type of an XQuery/XPath expression, the *sequence*, which can contain XML nodes, atomic values, or both, does not exist in XPath 1.0. A 1.0 expression can only produce a node-set (containing zero or more XML nodes), or a single atomic value.
- Unlike an XQuery/XPath sequence, which can contain any desired items in any desired order, an XPath 1.0 node-set has no guaranteed order and, like any set, does not allow multiple appearances of the same item.

Note

The libxml2 library does seem to always return node-sets to Postgres Pro with their members in the same relative order they had in the input document. Its documentation does not commit to this behavior, and an XPath 1.0 expression cannot control it.

- While XQuery/XPath provides all of the types defined in XML Schema and many operators and functions over those types, XPath 1.0 has only node-sets and the three atomic types `boolean`, `double`, and `string`.
- XPath 1.0 has no conditional operator. An XQuery/XPath expression such as `if ( hat ) then hat / @size else "no hat"` has no XPath 1.0 equivalent.
- XPath 1.0 has no ordering comparison operator for strings. Both `"cat" < "dog"` and `"cat" > "dog"` are false, because each is a numeric comparison of two NaNs. In contrast, `=` and `!=` do compare the strings as strings.
- XPath 1.0 blurs the distinction between *value comparisons* and *general comparisons* as XQuery/XPath define them. Both `sale/@hatsize = 7` and `sale/@customer = "alice"` are existentially quantified comparisons, true if there is any `sale` with the given value for the attribute, but `sale/@taxable = false()` is a value comparison to the *effective boolean value* of a whole node-set. It is true only if no `sale` has a `taxable` attribute at all.
- In the XQuery/XPath data model, a *document node* can have either document form (i.e., exactly one top-level element, with only comments and processing instructions outside of it) or content form (with those constraints relaxed). Its equivalent in XPath 1.0, the *root node*, can only be in document form. This is part of the reason an `xml` value passed as the context item to any Postgres Pro XPath-based function must be in document form.

The differences highlighted here are not all of them. In XQuery and the 2.0 and later versions of XPath, there is an XPath 1.0 compatibility mode, and the W3C lists of [function library changes](#) and [language changes](#) applied in that mode offer a more complete (but still not exhaustive) account of the differences. The compatibility mode cannot make the later languages exactly equivalent to XPath 1.0.

D.3.1.3. Mappings between SQL and XML Data Types and Values

In SQL:2006 and later, both directions of conversion between standard SQL data types and the XML Schema types are specified precisely. However, the rules are expressed using the types and semantics of XQuery/XPath, and have no direct application to the different data model of XPath 1.0.

When Postgres Pro maps SQL data values to XML (as in `xmlelement`), or XML to SQL (as in the output columns of `xmltable`), except for a few cases treated specially, Postgres Pro simply assumes that the XML data type's XPath 1.0 string form will be valid as the text-input form of the SQL datatype, and

conversely. This rule has the virtue of simplicity while producing, for many data types, results similar to the mappings specified in the standard.

Where interoperability with other systems is a concern, for some data types, it may be necessary to use data type formatting functions (such as those in [Section 9.8](#)) explicitly to produce the standard mappings.

D.3.2. Incidental Limits of the Implementation

This section concerns limits that are not inherent in the libxml2 library, but apply to the current implementation in Postgres Pro.

D.3.2.1. Only `BY VALUE` Passing Mechanism Is Supported

The SQL standard defines two *passing mechanisms* that apply when passing an XML argument from SQL to an XML function or receiving a result: `BY REF`, in which a particular XML value retains its node identity, and `BY VALUE`, in which the content of the XML is passed but node identity is not preserved. A mechanism can be specified before a list of parameters, as the default mechanism for all of them, or after any parameter, to override the default.

To illustrate the difference, if `x` is an XML value, these two queries in an SQL:2006 environment would produce true and false, respectively:

```
SELECT XMLQUERY('$a is $b' PASSING BY REF x AS a, x AS b NULL ON EMPTY);
SELECT XMLQUERY('$a is $b' PASSING BY VALUE x AS a, x AS b NULL ON EMPTY);
```

Postgres Pro will accept `BY VALUE` or `BY REF` in an `XML EXISTS` or `XMLTABLE` construct, but it ignores them. The `xml` data type holds a character-string serialized representation, so there is no node identity to preserve, and passing is always effectively `BY VALUE`.

D.3.2.2. Cannot Pass Named Parameters to Queries

The XPath-based functions support passing one parameter to serve as the XPath expression's context item, but do not support passing additional values to be available to the expression as named parameters.

D.3.2.3. No `XML (SEQUENCE)` Type

The Postgres Pro `xml` data type can only hold a value in `DOCUMENT` or `CONTENT` form. An XQuery/XPath expression context item must be a single XML node or atomic value, but XPath 1.0 further restricts it to be only an XML node, and has no node type allowing `CONTENT`. The upshot is that a well-formed `DOCUMENT` is the only form of XML value that Postgres Pro can supply as an XPath context item.

Appendix E. Release Notes

The release notes contain the significant changes in each Postgres Pro Standard release, with major features and migration issues listed at the top. The release notes do not contain changes that affect only a few users or changes that are internal and therefore not user-visible. For example, the optimizer is improved in almost every release, but the improvements are usually observed by users as simply faster queries.

E.1. Postgres Pro Standard 16.10.1

Release Date: 2025-09-16

E.1.1. Overview

This release is based on PostgreSQL 16.10 and Postgres Pro Standard 16.9.1. All improvements inherited from PostgreSQL 16.10 are listed in [PostgreSQL 16.10 Release Notes](#). Other major changes and enhancements are as follows:

- Improved performance by introducing a more efficient synchronization primitive instead of previously used spinlocks for a shared invalidation message queue, which allows avoiding a bottleneck. This may be useful for 1C.
- Updated [CREATE DATABASE](#), [createdb](#), and [initdb](#) to display an information message when the value of [lc_collate](#) is used as the default for [icu_locale](#) or `--icu-locale`.
- Optimized the behavior when working with the [COALESCE](#) function. Now this function is replaced with one of its arguments if all other arguments were evaluated to `null`. This allows improving the selectivity of query clauses and producing better execution plans.
- Introduced the following changes to the implementation of [crash_info](#):
 - Added the [crash_info_timer](#), [crash_info_timer_interval](#), and [crash_info_query_threshold](#) configuration parameters that allow profiling long queries in [crash_info](#) output files.
 - Extended the diagnostic information that the [crash_info_dump](#) configuration parameter can specify to write in case of a backend crash. By default, now the general information on the signal is dumped and for Linux x64, also the information on the processor state and bytes near RIP (return instruction pointer). All this ensures better diagnostics, in particular, in case of `SIGILL` (illegal instruction) signals. The way of dumping stack files in case of crashes has also been changed for Linux x64. Besides, `memory_context` has been removed from the default list of sources to be dumped in order to avoid failures that could occur when writing the diagnostic information.
- Fixed an issue in `LISTEN/NOTIFY` queue handling, which caused failure to obtain transaction status. Previously, `VACUUM FREEZE` could advance `datfrozenxid` too far forward.
- Fixed an issue where the planner could choose non-optimal execution plans for queries that use the `LIKE` operator with the `mchar` data type.
- Added support for Debian 13, Red Hat Enterprise Linux 10, Rocky Linux 10, Oracle Linux 10, and AlmaLinux 10.
- Ended support for Ubuntu 20.04/24.10.
- Added the [wal2json](#) extension for logical decoding that converts database changes from the write-ahead log (WAL) into JSON format.
- Upgraded [aqo](#) to provide the following bugfixes:
 - Added the `tmpoids` field to the [aqo_data](#) view and the `tmpoids` parameter to the [aqo_data_update](#) function to support queries that involve temporary tables along with persistent tables.
 - Fixed the race condition when calling the [aqo_cleanup](#) function from different sessions.
 - Fixed an issue where `aqo` learning data was not saved for queries that use materialization.

- Fixed an issue in `aqo`, which could lead to a standby crash with SIGABRT if the standby had a different `aqo` version than the primary.
- Upgraded `auto_explain` to move the planning time of a query in the output to a separate line under the planner tree, as in the `EXPLAIN` output. With the former location of the planning time in the output, `pgbadger` could not recognize the information on a query and therefore did not include it in the report.
- Updated `pg_pathman` to fix an issue with partition access handling. The issue could cause commands that reuse the same query plan, for example, in PL/pgSQL, to fail with errors such as “relation with OID `NNNN` does not exist”.
- Upgraded `pg_proaudit` to provide the following enhancements:
 - Added support for CEF format for event log files.
 - Adjusted `pg_proaudit` output. `xid` and `vxid` fields are no longer displayed if they are zero.
- Upgraded `pg_probackup` to version 2.8.10, which provides the following new features, optimizations, and bug fixes:
 - Added the `--wal-tree` option for the `add-instance` command to store archived WAL files in a tree-like structure. This improves WAL operation performance with large volumes of logs.
 - Added the `postgres-edition` field to the `show` command output in the `JSON` format to display DBMS edition information.
 - Improved the `--dry-run` option operation during tablespace recovery. The operation estimation and plan output are now more precise.
 - Fixed an issue related to the retention window calculation. The time value is now taken from the host where `pg_probackup` is running. The retention window is now calculated correctly even with the timezone differences between the servers.
 - Fixed a problem with the `archive-get` command operation. The `pbk_prefetch` directory is now created with correct access rights, inheriting permissions from `PGDATA`.
 - Fixed false failure of the `checkdb` command in the remote mode during concurrent `TRUNCATE` operations or table drops on standby nodes.
- Fixed the following issues in the `pgpro_bindump` module:
 - Fixed potential `pg_probackup3` failure caused by temporary tables during backup validation using the `pgpro_bindump` module in the PRO mode.
 - Fixed a memory leak in `pg_probackup3` using the `pgpro_bindump` module for PTRACK operations.
 - Fixed an issue that could cause infinite looping in `pg_probackup3` when using the `pgpro_bindump` module.
 - Fixed an issue with multi-timeline backup in the PTRACK mode in `pg_probackup3` using the `pgpro_bindump` module in the PRO mode.
- Upgraded `pgpro_pwr` to version 4.10, which completely redesigns the report and supports PostgreSQL 18.
- Upgraded `pgpro_stats` to provide the following improvements and bug fixes:
 - Implemented the ability to track utility commands by their `query_id`, as it is done in `pg_stat_statements`. Previously, utility commands were tracked based on strict comparison of their textual query strings, and therefore could not be properly normalized.
 - Fixed a segmentation fault that could occur when defining custom metrics. The error originated from a memory allocation issue, which was fixed.
- Fixed an issue with incorrect configuration parameter values specified when using the `1c.tune` preset of the `pgpro_tune` utility.

- Upgraded [pg_query_state](#) to version 1.2 to add the [pg_progress_bar](#) and [pg_progress_bar_visual](#) functions that allow monitoring the current progress of query execution.
- Upgraded [rum](#) to provide the following bugfixes:
 - Fixed a segmentation fault caused by invalid memory access when a buffer pointer was used after the underlying buffer was modified by another thread.
 - Fixed an index scan infinite loop when using multiple `ORDER BY` clauses.

E.1.2. Migration to Version 16.10.1

If you are upgrading from Postgres Pro Standard based on the same PostgreSQL major version, it is enough to install the new version into your current installation directory.

Important

If you used a previous version of [aqo](#) and need to upgrade it, after the upgrade of the primary server, the standby servers may have a different aqo version.

To avoid any related issues, disable aqo by setting `aqo.enable` and `aqo.wal_rw` to `off` first on the primary server and then on the standby servers. After the upgrade completes successfully, re-enable aqo by setting `aqo.wal_rw` and `aqo.enable` to `on` first on the standby servers and then on the primary server.

ABI versions may change between minor releases of Postgres Pro. If this is the case, and you see the `ABI mismatch` error when trying to run your extension, make sure to install a new version of the extension supplied with a new release of Postgres Pro, or recompile your third-party extension to be able to use it with the current version of Postgres Pro.

If you take backups using `pg_probackup` and you have previously upgraded it to version 2.8.0 or 2.8.1, make sure to upgrade it to version 2.8.2 or higher and retake a full backup after upgrade, since backups taken using those versions might be corrupted. If you suspect that your backups taken with versions 2.8.0 or 2.8.1 may be corrupted, you can validate them using version 2.8.2.

To migrate from PostgreSQL or a Postgres Pro Standard release based on a previous PostgreSQL major version, see the instructions in [Postgres Pro Standard 16.0.1 Release Notes](#).

E.2. Postgres Pro Standard 16.9.1

Release Date: 2025-05-29

E.2.1. Overview

This release is based on PostgreSQL 16.9 and Postgres Pro Standard 16.8.1. All improvements inherited from PostgreSQL 16.9 are listed in [PostgreSQL 16.9 Release Notes](#). Other major changes and enhancements are as follows:

- Added the [enable_alternative_sorting_cost_model](#) configuration parameter, which allows you to enable or disable the query planner's use of alternative model for estimating the cost of tuple sorting.
- Added the [enable_any_to_lateral_transformation](#) configuration parameter that allows enabling or disabling transformation of `ANY` subqueries into `LATERAL` joins.
- Added the experimental feature that enables the [parallel query execution](#) mechanism for queries that involve at least one temporary table. It can be enabled using the new [enable_parallel_temptables](#) configuration parameter. This feature cannot be used in production for now. Also, added the new [write_page_cost](#) configuration parameter that allows estimating the cost of flushing temporary table pages to disk. It will only work if `enable_parallel_temptables` is enabled. These parameters are useful for 1C.

- Introduced the following changes to the implementation of [crash_info](#):
 - Added handling of `SIGILL` signals to `crash_info` processing.
 - Added details, like process start time and query text at planning, to `crash_info` output files.
 - Fixed incorrect function names in the first 2-3 lines of `crash_info` backtrace stacks.
 - Fixed possible data truncation at the end of SQL query dump files. Previously, a buffer overflow during SQL query dumping could result in incomplete writes, causing truncated data at the end of files produced by `crash_info`.
 - Fixed handling of crash information signals (sent using the `kill` command) by backends. Previously, the first signal would flush `crash_info` information to the log, but the process would continue running without producing a core dump, even if configured, and only the second signal would terminate the backend and generate the core dump as expected.
- Fixed an issue with missing statistics about vacuuming when multiple index vacuum workers are used.
- Added the [daterange_inclusive](#) extension, which allows you to include the upper bound of a time range in output.
- Added the [pg_probackup3](#) solution for backup and recovery of Postgres Pro database clusters. Refer to the [pg_probackup3 release notes](#) for more details.
- Added the [pgpro_bindump](#) module to manage backup and restore operations. This module implements specialized replication commands for an extended replication protocol, has its own format for archiving files, and does not require SSH connection. It is designed specifically for use with the [pg_probackup3](#) utility.
- Added the new [pgpro_tune](#) utility for automatic tuning of Postgres Pro configuration parameters.
- Added a new `PGPRO_TUNE` environment variable to `initdb`, which specifies whether to use [pgpro_tune](#) without modifying command-line options directly.
- Removed the `--tune` option from `pg-setup`. Use the new [pgpro_tune](#) utility instead.
- Upgraded [oracle_fdw](#) to provide the following enhancements and bug fixes:
 - Increased line size for EXPLAIN output as some Oracle catalog queries have long filter conditions. The line size was increased to the value of 3000.
 - Fixed a crash with column options on non-existing columns. If the Oracle table has fewer columns than the Postgres Pro and one of these extra columns has a column option set, `oracle_fdw` would write past the end of an array, leading to memory corruption and crashes. Now options for such columns are ignored.
- Upgraded [pg_proaudit](#) to provide the following enhancements and bug fixes:
 - Added new object types: `CATALOG RELATION` and `CATALOG FUNCTION`.
 - Added new event fields: `UUID`, `XID`, and `VXID`. Now it is possible to identify an event by its `UUID` and transaction IDs (if applicable).
 - The behavior of the `pg_proaudit.log_catalog_access` configuration parameter was corrected to reflect the new logic of logging for system catalog objects.
 - Changed the logic of handling disconnection events. Now these events are associated with the corresponding authentication events, so the disconnection events will be logged even in the case when the rule is removed after authentication, but before disconnect.
 - Fixed an issue where the `DISCONNECT` event type was not logged for a user who was a member of the role that was set in the logging rule.
 - Fixed the bug that caused a log entry to be written to an incorrect log file when log file rotation was configured.

- Fixed an issue with `pg_proaudit` failing to log schema creation events.
- Corrected the behavior of the `logger` process when deleting a role from a parallel session configured by the rule.
- Upgraded `pg_probackup` to version 2.8.9, which provides the following new features, optimizations, and bug fixes:
 - Added the `maintain` command to resolve issues that can occur during a forced backup termination.
 - Added the `--lock-lifetime` option that sets the timeout for locks. This option is useful for computational environments with a slow network.
 - Stabilized retaining the initial permissions for directories when running the `init` command.
 - Stabilized the `checkdb` command on a remote host.
 - Improved the stability of the point-in-time recovery (PITR) with validation.
 - Fixed an incorrect behavior that could occur when launching the wait for a WAL streaming thread in the ARCHIVE WAL delivery mode.
- Upgraded `pgpro_pwr` to version 4.9, which mainly provides optimizations and bug fixes. Notable changes are as follows:
 - Added support for `pgpro_stats` 1.9.
 - Added a possibility to define the mode of collecting relation sizes globally through the `pg-pro_pwr.relsizes_collect_mode` extension parameter or for a server through the `set_server_size_sampling` function parameter.
 - Enabled fine-tuning the server statistics collection by calling the `set_server_setting` function. It allows you to define which statistics should be collected.
 - Added a preview of storage parameters for tables and indexes in the “Schema object statistics” report section.
- Upgraded `pgpro_stats` to version 1.9, which provides the following bug fixes and improvements:
 - Enhanced session tracing to provide more information. Specifically, the new `time_info` filter attribute controls inclusion of additional information in the session-tracing output, and the `pg-pro_stats.trace_query_text_size` configuration parameter can limit the size of the query in the session-tracing output.
 - Aligned the names of the `explain_*` filter attributes of the session tracer with the names of session-tracing configuration parameters.
 - Changed the format of the statistics dump file and the corresponding save/load routines.
 - Implemented turning off the session tracer functionality when no session-tracing filters are specified.
 - Prohibited inclusion of both `pgpro_stats` and `pg_stat_statements` in the list of `shared_preload_libraries`. If both are included, the database server will not start.
- Upgraded the `pg_wait_sampling` extension to provide the following bug fixes:
 - Fixed an issue where GUC variables could be overridden when using parallel workers.
 - Fixed an issue with malformed samples caused by a race condition when `pg_wait_sampling.sample_cpu` is disabled.

E.2.2. Migration to Version 16.9.1

If you are upgrading from Postgres Pro Standard based on the same PostgreSQL major version, it is enough to install the new version into your current installation directory.

ABI versions may change between minor releases of Postgres Pro. If this is the case, and you see the `ABI mismatch` error when trying to run your extension, make sure to install a new version of the extension supplied with a new release of Postgres Pro, or recompile your third-party extension to be able to use it with the current version of Postgres Pro.

If you take backups using `pg_probackup` and you have previously upgraded it to version 2.8.0 or 2.8.1, make sure to upgrade it to version 2.8.2 or higher and retake a full backup after upgrade, since backups taken using those versions might be corrupted. If you suspect that your backups taken with versions 2.8.0 or 2.8.1 may be corrupted, you can validate them using version 2.8.2.

To migrate from PostgreSQL or a Postgres Pro Standard release based on a previous PostgreSQL major version, see the instructions in [Postgres Pro Standard 16.0.1 Release Notes](#).

E.3. Postgres Pro Standard 16.8.1

Release Date: 2025-02-27

E.3.1. Overview

This release is based on PostgreSQL 16.8 and Postgres Pro Standard 16.6.1. All improvements inherited from PostgreSQL 16.8 are listed in [PostgreSQL 16.8 Release Notes](#). Other major changes and enhancements are as follows:

- Added details, like current working directory, the `PGDATA` directory, etc., to `crash_info` output files.
- Added the increased security requirements for the `CREATE PROFILE` command. Now the `PASS-WORD_REQUIRE_COMPLEX` parameter requires characters from three different groups. Also, all characters of languages without case distinction (Hindi, Chinese, etc.) in the UTF-8 encoding are considered lowercase.
- Fixed an issue where `crash_info` could fail to write diagnostic files when handling a stack overflow. Previously, the signal handler ran on the same stack that had overflowed, which could prevent it from executing due to lack of available stack space. Now the handler runs on an alternate signal stack.
- Fixed a memory context issue, which could previously cause emitting garbage in logs instead of the host and port details when disconnecting from the remote server.
- Fixed an issue that could occur when a custom scan was used, which could cause an incorrect state of the query plan and could result in an error when `pgpro_stats` was involved.
- Fixed an issue where roles without explicitly set `VALID UNTIL` attribute and associated with a profile that had `PASSWORD_GRACE_TIME` set to 0 and `PASSWORD_LIFE_TIME` set to `UNLIMITED` incorrectly received password expiration warnings. Now they are correctly considered valid indefinitely.
- Optimized `fasttrun` to skip unnecessary truncate operations on empty temporary relations.
- Upgraded `mamonsu` to version 3.5.11 to provide support for `pgpro_stats` version 1.8.
- Upgraded `pgbadger` to version 13.0.
- Upgraded `pgbouncer` to version 1.24.0.
- Upgraded `pg_portal_modify` to version 0.3.5.
- Upgraded `pg_proaudit` to provide the following enhancements and bug fixes:
 - Added a new event field: session user name. Now an event contains the information about both `session_user` and `current_user` attributes of an SQL session.
 - Added support for new event classes: `ALL_DDL_NONTEMP` and `ALL_DML_NONTEMP`. The scope of these classes is limited to the objects that are not contained in `pg_temp_nnn` temporary schemas.
 - Fixed logging of `SELECT FOR UPDATE` and `SELECT FOR KEY SHARE` events as `SELECT`, rather than `UPDATE`.
- Upgraded `pg_probackup` to version 2.8.7, which provides the following optimizations and bug fixes:

- Fixed an issue of the multi-threaded file copying technique that prevents repeated copying of one file. This issue could previously stop the backup creation under high load on the server.
- Reduced the log level for “checking WAL file name” messages that are issued when the `show` with the `--archive` option is executed from `INFO` to `VERBOSE`.
- Updated the `add-instance` command logic to make the `-D` option that specifies the path to the catalog mandatory. `add-instance` no longer relies on the `PGDATA` environment variable for the catalog location, but requires explicitly specifying the path to the catalog as the command option.
- Upgraded [pgpro_pwr](#) to version 4.8, which provides new features and bug fixes. Notable changes are as follows:
 - Added tracking of extension versions installed in the cluster through a new report section.
 - Added a possibility to hide data for certain databases in the report. To this end, a new parameter that accepts an array of databases to be excluded was added to report generation functions.
- Upgraded [pgpro_stats](#) to version 1.8.1, which provides the following bug fixes and improvements:
 - Fixed an issue in that could occur during session tracing and cause errors “could not write file “pg_stat/pgpro_stats_filters.trace.tmp”: No such file or directory”. Concurrent writing from different sessions to a trace file is fixed now, so processes can write to the trace file in parallel without collisions.
 - Implemented an optimization that lowers the locking time in some cases when copying metrics from the local memory to the shared memory.
- Upgraded [pg_variables](#). The `DISCARD ALL` command now discards all packages and variables in `pg_variables`.
- Upgraded the [rum](#) module to update an error message for an error that can occur in the case when a `SELECT` query uses `ORDER BY`.

E.3.2. Migration to Version 16.8.1

If you are upgrading from Postgres Pro Standard based on the same PostgreSQL major version, it is enough to install the new version into your current installation directory.

ABI versions may change between minor releases of Postgres Pro. If this is the case, and you see the `ABI mismatch` error when trying to run your extension, make sure to install a new version of the extension supplied with a new release of Postgres Pro, or recompile your third-party extension to be able to use it with the current version of Postgres Pro.

If you take backups using `pg_probackup` and you have previously upgraded it to version 2.8.0 or 2.8.1, make sure to upgrade it to version 2.8.2 or higher and retake a full backup after upgrade, since backups taken using those versions might be corrupted. If you suspect that your backups taken with versions 2.8.0 or 2.8.1 may be corrupted, you can validate them using version 2.8.2.

To migrate from PostgreSQL or a Postgres Pro Standard release based on a previous PostgreSQL major version, see the instructions in [Postgres Pro Standard 16.0.1 Release Notes](#).

E.4. Postgres Pro Standard 16.6.1

Release Date: 2024-11-28

E.4.1. Overview

This release is based on PostgreSQL 16.6 and Postgres Pro Standard 16.4.1. All improvements inherited from PostgreSQL 16.6 are listed in [PostgreSQL 16.6 Release Notes](#). Other major changes and enhancements are as follows:

- Added the ability to form the `MergeAppend` operation instead of `Append`, which allows omitting additional sorting needed to ensure that the data is in fact sorted. Now `MergeAppend` is formed specify-

ing the columns to sort by. The new ability applies only when the `enable_appendorpath` option is set to `ON`.

- Allowed transformation of correlated `IN` subqueries into joins.
- Implemented the ability to `dump` the state of a single backend process by sending the dump signal.
- Changed the error level to calculate the statistics on `vacuum` interrupts to `ERROR (PGERROR)` only. Calculating vacuum interrupts for the `PANIC` error level could cause unpredictable system behavior, and the statistics could not be calculated anyway because of the server crash.
- Deprecated the ability to create constructs using `JSON_EXISTS()` with the `RETURNING` clause. This syntax is not supported by the SQL/JSON standard, which states that the `JSON_EXISTS()` predicate should only return `TRUE`, `FALSE`, or `UNKNOWN`.
- Fixed a segmentation fault, which could occur while executing the `COPY TO` command when using the `online_analyze` module.
- Fixed an issue to avoid potential stack overflow in scenarios involving a large number of subtransactions. Now when handling the process of committing a transaction, iteration is used instead of tail recursion.
- Fixed a memory leak that could occur when the `EXPLAIN` command's output produced over 64 columns.
- Fixed an issue where `EXPLAIN ANALYZE` showed incorrect counts of inserted and conflicted tuples during row inserts with conflicting primary keys when using `ON CONFLICT DO NOTHING`.
- Fixed an issue that could slow down query execution. The reason was that the optimizer selected a suboptimal index due to the lack of its cost estimation after removing redundant clauses with the `enable_appendorpath` option set to `ON`.
- Added support for ARM architecture for Red OS Murom 8.
- Ended support for Ubuntu 23.10 and added support for Ubuntu 24.10.
- Upgraded `aqo` to provide the following enhancements and bugfixes:
 - Introduced the `aqo` sandbox mode, which allows working in an isolated environment without touching the main `aqo` knowledge base. This mode can be turned on either on a primary or a standby node by setting `aqo.sandbox` to `on`.
 - Enhanced `aqo` wide search (`aqo.wide_search = on`) to utilize data from multiple neighbors simultaneously. Also, revised its interaction with `aqo.min_neighbors_for_predicting` to allow queries with fewer than the specified number of data samples to participate in wide search. Previously, such queries were excluded from consideration.
 - Fixed an array index out-of-bounds issue in the `aqo` smart statement timeout update logic, as well as incorrect statistics insertion into `aqo_query_stats` when the arrays were full.
- Upgraded `mamonsu` to version 3.5.9, which provides optimizations and bug fixes. Notable changes are as follows:
 - Added support for systems where `setuptools` version greater than 67.7.2 is installed.
 - Ended the use of dotted `user:group` specification at the RPM pre-install stage.
- Upgraded the ODBC driver to version 17.00.0002.
- Upgraded `oracle_fdw` to version 2.7.0.
- Upgraded `orafce` to version 4.13.5.
- Upgraded `pg_filedump` to version 17.1, which specifically fixed an issue that could cause `pg_filedump` to crash with a segmentation fault when handling incomplete pages.
- Upgraded `pg_integrity_check` to display actual checksum values, if the checksums differ, only with the `--verbose` option.

- Upgraded `pg_portal_modify` to version 0.3.4.
- Upgraded `pg_proaudit` to provide the following optimizations and bug fixes:
 - Added logging of security events related to operations with profiles: `CREATE PROFILE`, `ALTER PROFILE`, and `DROP PROFILE`.
 - Changed the distribution of security events related to functions and stored procedures among the groups of security events: the `ALL_DDL` group now includes no events related to functions and stored procedures, `ALL_PROC` includes `CREATE`, `ALTER`, and `DROP`, while `ALL_DML` includes `EXECUTE`.
 - Fixed logging of security events on partitioned tables. Now the `SELECT/UPDATE/INSERT/DELETE/TRUNCATE` events on a partitioned table get logged if logging rules imply logging of appropriate events for this table. Previously, only events on individual partitions were logged.
 - Fixed compatibility with the connection pooler. Previously, issues could be encountered when logging `AUTHENTICATE` and `DISCONNECT` security events.
- Upgraded `pg_probackup` to version 2.8.5, which provides the following optimizations and bug fixes:
 - Enabled the output of the `version` command in the JSON format using `--format=json`.
 - Added the `--all` option to the `amcheck` command, which allows performing all the checks in a single command.
 - Added support for the `include` parameter in the configuration file. The contents of the file specified in `include` gets added to the configuration file instead of this parameter.
 - Added a possibility to specify an individual number of threads for execution of a backup and its subsequent validation by specifying the `--backup-threads` and `--validate-threads` option, respectively.
 - Changed the priority of setting `PGDATA` and `BACKUP_PATH`. Now the values from the command-line options take precedence.
 - Added validation of WAL files for backups to be merged by the `merge` command.
 - An error message that was issued when the `validate` command run with the `--wal` option found an archive in the `DEGRADED` status has been replaced with a warning since backups in this status do not affect the restore correctness as a whole.
 - Fixed an issue that could occur if the command line was too long.
 - Fixed an issue that could occur during validation or restore when the PITR from a previous timeline was performed.
- Upgraded `pgpro_controldata` to version 17.1.0.
- Upgraded `pgpro_stats` to version 1.8, which supports Postgres Pro 17. Notable changes are as follows:
 - Updated `pgpro_stats_statements` and `pgpro_stats_totals` views to include fields added to `pg_stat_statements`. Related functions were updated accordingly.
 - Streamlined access to views and functions. Specifically, access to the `pgpro_stats_archiver`, `pgpro_stats_vacuum_database`, `pgpro_stats_vacuum_tables`, and `pgpro_stats_vacuum_indexes` views was granted to all users. Previously, these views required explicitly granting access rights. Access to execution of the `pgpro_stats_trace_reset` function, which could previously be executed by any user, was restricted to superusers.
 - Eliminated an excessive check of holding the lock when accessing the hash table of session-tracing filters.
 - Fixed processing of the `pgpro_stats.stats_temp_directory` configuration parameter. Previously after the server restart for changes to this parameter value to take effect, the fatal error “pfree called with invalid pointer” could occur when processing this parameter.

- Upgraded [pgpro_pwr](#) to version 4.7, which provides new features, optimizations and bug fixes. Notable changes are as follows:
 - A *subsample* feature to collect relatively fast changing data.
 - New report tables, specifically regarding session states.
 - Support for new Postgres Pro 17 statistics.
 - A possibility not to reset statistics of the statistics collecting extension during taking a sample.
 - The change of the type for the field that tracks transaction IDs in a certain table from `xid` to `text`. The use of the `xid` type could previously cause a failure of [pg_upgrade](#) when upgrading from Postgres Pro Standard to Postgres Pro Enterprise.
- Upgraded [pg_repack](#) to version 1.5.1.
- Upgraded [pg_wait_sampling](#) to provide tracking of subquery IDs and utility statements and to add the new `pg_wait_sampling.sample_cpu` parameter, which allows specifying the sampling mode that determines whether to perform sampling of on-CPU backends.
- Upgraded the PLV8 extension to version 3.2.3.
- Upgraded [PTRACK](#) to prevent possible issues with PTRACK backups by setting the `ptrack.map` file for automatic deletion when PTRACK is disabled.
- Upgraded `tds_fdw` to version 2.0.4.

E.4.2. Migration to Version 16.6.1

If you are upgrading from Postgres Pro Standard based on the same PostgreSQL major version, it is enough to install the new version into your current installation directory.

ABI versions may change between minor releases of Postgres Pro. If this is the case, and you see the `ABI mismatch` error when trying to run your extension, make sure to install a new version of the extension supplied with a new release of Postgres Pro, or recompile your third-party extension to be able to use it with the current version of Postgres Pro.

If you take backups using `pg_probackup` and you have previously upgraded it to version 2.8.0 or 2.8.1, make sure to upgrade it to version 2.8.2 or higher and retake a full backup after upgrade, since backups taken using those versions might be corrupted. If you suspect that your backups taken with versions 2.8.0 or 2.8.1 may be corrupted, you can validate them using version 2.8.2.

To migrate from PostgreSQL or a Postgres Pro Standard release based on a previous PostgreSQL major version, see the instructions in [Postgres Pro Standard 16.0.1 Release Notes](#).

E.5. Postgres Pro Standard 16.4.1

Release Date: 2024-08-16

E.5.1. Overview

This release is based on PostgreSQL 16.4 and Postgres Pro Standard 16.3.2. All improvements inherited from PostgreSQL 16.4 are listed in [PostgreSQL 16.4 Release Notes](#). Other major changes and enhancements are as follows:

- Enhanced performance of segment search by implementing a new search strategy, allowing faster detection of the last segment.
- Implemented the interaction of the [PASSWORD_GRACE_TIME](#) profile parameter with the `VALID UNTIL` role attribute. Now if both of them are set, the warning about password expiration will be displayed.
- Prevented potential authentication delays due to locking by not updating role's last login time if the role's profile `USER_INACTIVE_TIME` is set to unlimited (see [Section 52.40](#) for details).
- Fixed an issue with nested loop parameters that forced Memoize to constantly purge the cache. This bugfix speeds up query execution.

- Fixed a bug that caused the optimizer to ignore columns from query conditions. Previously, when partially using a composite index, the number of rows could be overestimated, which led to an incorrect plan creation. The bug occurred due to a malfunction of the multi-column statistics elements.
- Fixed a bug in [ANALYZE](#) that could occur because it was impossible to display the `pg_statistic` system catalog. For the fix to work, if your database has indexes with `INCLUDE` columns, after upgrading Postgres Pro, it is recommended to do another `ANALYZE` for these columns.
- Added support for ALT 11.
- Ended support for Ubuntu 23.04.
- Upgraded the PostgreSQL ODBC driver to version 16.00.0005.
- Added the [hypopg](#) extension, which provides support for hypothetical indexes in Postgres Pro.
- Upgraded the [mchar](#) extension to fix a bug that caused the `mchar` and `mvarchar` data types to ignore control characters during string comparison.
- Added support for `COPY` to the [online_analyze](#) module.
- Upgraded [pg_proaudit](#) to provide the following optimizations and bug fixes:
 - Improved performance and added the `pg_proaudit.max_rules_count` parameter, which allows specifying the maximum number of rules allowed.
 - Corrected support of database names including uppercase symbols by the `pg_proaudit_set_rule` function.
- Upgraded [pg_probackup](#) to version 2.8.3, which fixes backup validation for databases containing an OID larger than 10^9 . Previously, the validation status could be displayed incorrectly in such cases.
- Upgraded [pg_filedump](#) to version 17.0, which provides optimizations and bug fixes. In particular, contents of meta pages for GIN and SP-GiST indexes are now displayed correctly, and an issue of lacking memory for encoding and decompression is resolved.
- Upgraded pgvector to version 0.7.4.
- Fixed incorrect behavior of [pg_wait_sampling](#) when used with the extended query protocol.

E.5.2. Migration to Version 16.4.1

If you are upgrading from Postgres Pro Standard based on the same PostgreSQL major version, it is enough to install the new version into your current installation directory.

If you take backups using `pg_probackup` and you have previously upgraded it to version 2.8.0 or 2.8.1, make sure to upgrade it to version 2.8.2 or higher and retake a full backup after upgrade, since backups taken using those versions might be corrupted. If you suspect that your backups taken with versions 2.8.0 or 2.8.1 may be corrupted, you can validate them using version 2.8.2.

To migrate from PostgreSQL or a Postgres Pro Standard release based on a previous PostgreSQL major version, see the instructions in [Postgres Pro Standard 16.0.1 Release Notes](#).

E.6. Postgres Pro Standard 16.3.2

Release Date: 2024-06-27

E.6.1. Overview

This release is based on Postgres Pro Standard 16.3.1 and provides the following changes:

- Fixed a bug in the backend composite type cache management. This bug could result in a segmentation fault or produce errors like “ERROR: record type has not been registered” during the process of selectivity estimation in query planning under the following conditions:

- The query contained at least one `JOIN` operator.
- The [enable_compound_index_stats](#) configuration parameter was enabled.
- The tables involved in the query had multi-column `INCLUDE` indexes.
- Upgraded orafce to version 4.10.3.
- Upgraded [pg_probackup](#) to version 2.8.2, which provides the following bug fixes:
 - Fixed an OID parsing issue where databases and tablespaces with relfilenodes greater than a billion were not included in backups.
 - Fixed an issue in enabling `pg_probackup` logging with the `--log-level-file` parameter, where the parameter value was written to the configuration file, but no directory for log files was created.

E.6.2. Migration to Version 16.3.2

If you are upgrading from Postgres Pro Standard based on the same PostgreSQL major version, it is enough to install the new version into your current installation directory.

Important

If you take backups using `pg_probackup` and you have previously upgraded it to version 2.8.0 or 2.8.1, make sure to upgrade it to version 2.8.2 or higher and retake a full backup after upgrade, since backups taken using those versions might be corrupted. If you suspect that your backups taken with versions 2.8.0 or 2.8.1 may be corrupted, you can validate them using version 2.8.2.

To migrate from PostgreSQL or a Postgres Pro Standard release based on a previous PostgreSQL major version, see the instructions in [Postgres Pro Standard 16.0.1 Release Notes](#).

E.7. Postgres Pro Standard 16.3.1

Release Date: 2024-05-23

E.7.1. Overview

This release is based on PostgreSQL 16.3 and Postgres Pro Standard 16.2.2. All improvements inherited from PostgreSQL 16.3 are listed in [PostgreSQL 16.3 Release Notes](#). Other major changes and enhancements are as follows:

- Disabled the system startup timeout by setting the `TimeoutSec` parameter to 0 in `systemd`. Previously, big databases could fail to start within the specified timeout.
- Reduced logging level during a specified restore point creation at a checkpoint timeout for inactive bases only. It allows removing excessive log messages.
- Fixed a bug resulting in error “cache lookup failed for collation 128”. Now, for the additional `INCLUDE` index columns, collation is ignored.
- Fixed an issue of not streaming certain data to a subscriber by a logical replication after executing the `ALTER PUBLICATION pub ADD TABLE tab` command. The root cause of the issue was an insufficient interlocking between `ALTER PUBLICATION` and taking a snapshot.
- Fixed two planner issues. An expression duplication issue previously caused underestimation of node selectivity and cost in some cases, which could lead to a choice of a suboptimal plan. Another issue — the selectivity overestimation for an `AppendOr` node was caused by its subnode selectivity overestimation and led to the plan cost overestimation.
- Added support for Astra Linux 1.8 and ended support for Astra Linux Orel 2.12 and Astra Linux Smolensk 1.6.

- Added support for Ubuntu 24.04.
- Added support for Red OS Murom 8.
- Upgraded [aqo](#) to version 2.1, which added the [aqo.wal_rw](#) configuration parameter to enable physical replication and allow complete aqo data recovery after failure.
- Added the [dbcopies_decoding](#) 1C module for updating database copies. It is implemented as a logical replication plug-in and provided in `postgrespro-std-16-contrib`.
- Upgraded [mamonsu](#) to version 3.5.8, which provides optimizations and bugfixes. Notable changes are as follows:
 - Added support for the Zabbix 6.4 API: handling of deprecated parameters for authentication requests.
 - Removed caching of the `pgsql.connections[max_connections]` metric.
 - Updated the default log rotation rules.
 - Prepared for support of Python 3.12.
 - Changed metric names of the `pg_locks` plugin. Be aware that the changes could break custom user-defined triggers and processing functions that use the `item.name` parameter.
 - Fixed type mismatch for `pgpro_stats` and `pg_wait_sampling`.
 - Fixed privileges for the `mamonsu` role created by `bootstrap`.
- Upgraded `orafce` to version 4.10.0.
- Upgraded [pg_probackup](#) to version 2.8.0, which provides new features, optimizations and bug fixes. Notable changes are as follows:
 - Added a possibility to limit the rate of disk writes using the option `--write-rate-limit=bitrate` (Mbps, Gbps).
 - Decreased the memory consumption when restoring long sequences of increments twice on average.
 - Added a possibility to validate only a WAL archive.
 - Extended the use of the `--dry-run` option for all `pg_probackup` commands.
 - Made creation of a temporary slot during backups in the STREAM mode the default behavior unless it is specified otherwise.
 - Changed the default compression algorithm to `zstd`. If `zstd` is not supported by the system, `lz4` has the next priority. The `--compress` option now sets the default values for `--compress-level` and `--compress-algorithm`.
- Added the `pgv_exists_elem` function to [pg_variables](#) that checks whether an element with a key exists in a general collection.
- Added the `pgvector` extension that provides vector similarity search for Postgres Pro.
- Upgraded [pgpro_stats](#) to version 1.7.1, which provides optimizations and bug fixes. Notable changes are as follows:
 - Added saving non-normalized plans to [pgpro_stats](#) for queries where previously no plans were saved.
 - Fixed an issue that hindered the monitoring when the `pgpro_stats_statements` view contained quite a few rows with the same values of `plan` and `queryid`, but different values of `planid`. The issue was caused by an error in parsing the plan tree containing a `T_Memoise` node.
- Upgraded [pgpro_pwr](#) to version 4.5.
- Fixed an error “ERROR: query failed: ERROR: tablespace “XXXX” does not exist” that could occur when the [pg_repack](#) command was trying to reorganize tables in a tablespace whose name started with a digit. The root cause of the issue was that `pg_repack` expected extra quotes.

E.7.2. Migration to Version 16.3.1

If you are upgrading from Postgres Pro Standard based on the same PostgreSQL major version, it is enough to install the new version into your current installation directory.

To migrate from PostgreSQL or a Postgres Pro Standard release based on a previous PostgreSQL major version, see the instructions in [Postgres Pro Standard 16.0.1 Release Notes](#).

E.8. Postgres Pro Standard 16.2.2

Release Date: 2024-03-06

E.8.1. Overview

This release is based on Postgres Pro Standard 16.2.1 and provides the following changes:

- Fixed an issue of reusing subplans or alternative plans already released from memory that were previously passed by reference. This is solved by prohibiting the cleaning of expressions in memory. The issue could manifest itself in “unrecognized node” errors.
- Fixed incorrect handling of equivalence classes, which could cause [aqo](#) to ignore some plan nodes in complex queries.

E.8.2. Migration to Version 16.2.2

If you are upgrading from Postgres Pro Standard based on the same PostgreSQL major version, it is enough to install the new version into your current installation directory.

To migrate from PostgreSQL or a Postgres Pro Standard release based on a previous PostgreSQL major version, see the instructions in [Postgres Pro Standard 16.0.1 Release Notes](#).

E.9. Postgres Pro Standard 16.2.1

Release Date: 2024-02-16

E.9.1. Overview

This release is based on PostgreSQL 16.2 and Postgres Pro Standard 16.1.1. All improvements inherited from PostgreSQL 16.2 are listed in [PostgreSQL 16.2 Release Notes](#). Other major changes and enhancements are as follows:

- Updated the default values of [default_toast_compression](#) and [wal_compression](#) to `lz4`. It speeds up WAL and TOAST processing and reduces disk space utilization.
- Added configuration parameters to enable getting information on crashes of a backend. The [crash_info](#) parameter turns on this functionality, while [crash_info_dump](#) and [crash_info_location](#) specify the contents and location of crash information files, respectively.
- Added `-m`, `-o`, and `-x` options to [initdb](#) for testing database upgrades with custom initial xid, multi-xid and multixid offset values. These options were previously available only in Postgres Pro Enterprise.
- Optimized memory consumption during selectivity estimation for each array element as compared to vanilla PostgreSQL.
- Fixed segmentation fault that could occur when executing queries or using the planner with `pg_pathman` running. `pg_pathman` did not pay attention to new fields in the `RangeTblEntry` (RTE) structure, which were not correctly initialized. By making a regular copy of a parent RTE, `pg_pathman` also copied pointers to parent equivalence classes or their members. This inconsistency affected query planning and caused the error.
- Fixed the race condition between the autovacuum worker and backend processes when clearing orphaned tables, which could manifest itself in “cache lookup failed for relation” errors. Now autovacuum locks the namespaces when clearing orphaned tables.

- Fixed an issue that could occur during installation of a Postgres Pro server on Debian-based systems included in a domain with the `postgres` user.
- Fixed the output of `pg-setup`, which erroneously displayed the locale from the `LANG` environment variable at cluster initialization. Now the message about locale is not displayed at this stage.
- Ended support for Rosa Enterprise Linux Server 7.
- Ended support for ROSA COBALT (server edition) based on Rosa platform 7.
- Upgraded `orafce` to version 4.9.1.
- Upgraded `pg_filedump` to version 16.1.
- Upgraded `pg_proaudit` to version 2.0, which provides the following major changes and enhancements:
 - Added new functions `pg_proaudit_set_rule` and `pg_proaudit_remove_rule` that allow creating and removing logging rules, respectively. These functions replaced `pg_proaudit_set_object`, `pg_proaudit_set_role`, `pg_proaudit_reset_object`, and `pg_proaudit_reset_role`.
 - Implemented the ability to log groups of events by specifying the respective value in the `event_type` argument.
 - Added the `comment` column in the `pg_proaudit_settings` view that displays the comment to describe the created logging rule.
 - Implemented the ability to log security events related to objects of the `PREPARED STATEMENT` type as well as events of the `DEALLOCATE`, `EXECUTE`, and `PREPARE` types.
 - Fixed an issue with incorrect logging of the `CREATE DATABASE`, `CREATE GROUP`, `CREATE ROLE`, `CREATE TABLESPACE`, and `CREATE USER` security events. Previously, these events were logged as `SUCCESS` after the syntax check and before the command execution itself. Now `SUCCESS` is written in the log when the command execution finishes, and if the command fails, it is marked as `FAILURE`.
- Upgraded `pg_probackup` to version 2.7.2, which provides optimizations and bug fixes:
 - Fixed an issue that occurred during an incremental backup when a table that was not yet copied got removed from CFS.
 - Fixed the order of processing WAL files by the `archive-push` command when the number of WAL files exceeds the specified `--batch-size`.
 - Fixed an error “WAL segment is absent” that could occur when the size of a WAL record being logged exceeded the size of a WAL segment.
- Upgraded `pg_repack` to version 1.5.0.
- Upgraded `pg_variables`, which now provides iterator functionality for any collections, as well as functions to work with general collection variables. These functions allow accessing collection elements by a key that can have either integer or text type. These enhancements facilitate migration of Oracle code that processes collections.
- Upgraded `pgpro_stats` to version 1.7, which provides optimizations and bug fixes:
 - Similarly to a `pg_stat_statements` fix, changed `pgpro_stats` to read its “query texts” file in units of at most 1GB. Such large query text files are very unusual, but if they do occur, the previous coding would fail on Windows 64 (which rejects individual read requests of more than 2GB).
 - Implemented backward compatibility of `pgpro_stats_statements` and `pgpro_stats_totals` functions. Now a newer version of the `pgpro_stats` shared library can be safely used with old declarations of SQL functions. Previously such cases caused a server crash.
 - Fixed an issue that prevented output of database vacuuming statistics in the `pg_stats_vacuum_database` view. The fix requires updating this view every time you upgrade your server just by replacing the executables, as explained in a note right under the description of the view.

- Upgraded [pgpro_pwr](#) to version 4.4, which supports [pgpro_stats](#) 1.7, as well as adds more interactive features and substring-based filtering to the report.
- Upgraded the PLV8 extension to version 3.2.2.

E.9.2. Migration to Version 16.2.1

If you are upgrading from Postgres Pro Standard based on the same PostgreSQL major version, it is enough to install the new version into your current installation directory.

To migrate from PostgreSQL or a Postgres Pro Standard release based on a previous PostgreSQL major version, see the instructions in [Postgres Pro Standard 16.0.1 Release Notes](#).

E.10. Postgres Pro Standard 16.1.1

Release Date: 2023-11-30

E.10.1. Overview

This release is based on PostgreSQL 16.1 and Postgres Pro Standard 16.0.1. All improvements inherited from PostgreSQL 16.1 are listed in [PostgreSQL 16.1 Release Notes](#). Other major changes and enhancements are as follows:

- Added the [vacuum_update_datfrozenxid_only_when_needed](#) configuration parameter to improve the performance when vacuuming a large number of tables.
- Added support for ALT SP Release 10.
- Added support for Ubuntu 23.10.
- Fixed an internal issue that could arise when an index relation was moved to a different namespace similarly to a plain relation.
- Fixed too long planning that could take place when `JOIN` and index increased the number of variants to consider. Planning time was reduced by indexing equivalence classes and members of them.
- Upgraded [pgbouncer](#) to version 1.20.1.
- Upgraded [PTRACK](#) to version 2.5.1 Enterprise.

E.10.2. Migration to Version 16.1.1

If you are upgrading from Postgres Pro Standard based on the same PostgreSQL major version, it is enough to install the new version into your current installation directory.

To migrate from PostgreSQL or a Postgres Pro Standard release based on a previous PostgreSQL major version, see the instructions in [Postgres Pro Standard 16.0.1 Release Notes](#).

E.11. Postgres Pro Standard 16.0.1

Release Date: 2023-10-19

E.11.1. Overview

This release is based on PostgreSQL 16 and includes all the new features introduced in PostgreSQL 16. For their detailed description, see [PostgreSQL 16 Release Notes](#). Other major changes and enhancements are as follows:

- Added [system views](#) `pg_stats_vacuum_tables`, `pg_stats_vacuum_indexes` and `pg_stats_vacuum_database`, which show statistics about vacuuming tables, indexes and databases, respectively. These statistics were previously available through [pgpro_stats](#).
- Added new configuration parameters [pgpro_build](#), [pgpro_edition](#), and [pgpro_version](#), which report the Postgres Pro source code commit ID, edition, and server version respectively.

- Added [predefined roles](#):
 - `pg_create_tablespace`, which allows executing the `CREATE TABLESPACE` command without superuser rights.
 - `pg_manage_profiles`, which allows executing the `CREATE PROFILE`, `ALTER PROFILE`, and `DROP PROFILE` commands without superuser rights.
- Upgraded [aqo](#) to version 2.0, which provides the following major changes and enhancements:
 - The configuration is streamlined. Now aqo behavior mainly depends on three configuration parameters: `aqo.enable`, `aqo.mode` and `aqo.advanced`, which respectively define aqo state, operation mode and whether statistics is isolated per query.
 - The default values of configuration parameters set the recommended basic mode, where statistics is collected for plan nodes, and the collected machine learning data is used to correct the cardinality estimation error for all queries whose plan might contain a certain plan node.
 - aqo can now work with multiple databases independently.
 - Executing the `DROP/CREATE EXTENSION` command is now sufficient to instantly disable/enable aqo at the database level.
 - Memory consumption is reduced.
- Upgraded [oracle_fdw](#) to version 2.6.0.
- Upgraded `orafce` to version 4.6.1.
- Upgraded [pg_integrity_check](#), which now provides three new options.
- Upgraded [pg_proaudit](#) to version 1.2, which provides the following changes:
 - Changed the name of the `CONNECT` events recorded by `pg_proaudit` to `AUTHENTICATE`.
 - Removed the `pg_proaudit.syslog_facility` and `pg_proaudit.syslog_ident` configuration parameters. Instead, the [syslog_ident](#) and [syslog_facility](#) parameters can be used.
 - Records in the syslog are now marked with `AUDIT` for clear identification.
 - Added the `db_name` argument for functions that add and delete the logging settings. This argument allows specifying the name of the database for which security events need to be logged. Also, the `role_oid` argument can now be passed with `NULL` to enable logging actions for all users.
- Upgraded [pg_probackup](#) to version 2.6.6, which in particular improved stability of the `catchup` command.
- Upgraded [pgpro_pwr](#) to version 4.3, which introduced a role model and added a few report tables.
- Upgraded `tds_fdw` to version 2.0.3.

For the list of extension modules and utilities specific to Postgres Pro Standard, as well as the main user-visible core changes as compared to vanilla PostgreSQL, see [Section 2](#).

E.11.2. Migration to Version 16

You can migrate to Postgres Pro Standard 16 from the same or a previous version of PostgreSQL (that is supported by the upgrade method chosen) and from a previous version of Postgres Pro Standard or Postgres Pro Standard Certified. The same holds for migration to Postgres Pro Standard Certified 16. See [Section 17.6](#) for the methods to upgrade your database cluster. Consult the Postgres Pro Standard support team if you experience issues during migration. Backward migration is not supported. Note that migration from Postgres Pro Standard to Postgres Pro Standard Certified of the same major version (or vice versa) is an update between Postgres Pro compatible versions (see [Section 17.6](#) for more details).

To migrate from PostgreSQL or a Postgres Pro Standard release based on a previous PostgreSQL major version, make sure to install its latest available minor version and then perform a dump/restore using [pg_dumpall](#) or use the [pg_upgrade](#) utility.

If you choose to run `pg_upgrade`, make sure to initialize the new database cluster with compatible parameters. In particular, pay attention to the [checksum](#) settings in the cluster you are migrating from. If `pg_upgrade` creates any SQL files in its current directory, run these files to complete the upgrade.

When upgrading the installation from version 10 or lower, a dump/restore is recommended. In this case, you may have to resolve constraint violations manually. If this option is infeasible, you can still use `pg_upgrade`, but consult the Postgres Pro Standard support team since the integrity of indexes and constraints might be violated in some cases.

Note

To avoid conflicts, do not use the `postgrespro-std-16` package to install the new Postgres Pro binaries. Use the individual packages instead. In this case, server autostart needs to be enabled manually, if required. For details on the available packages, see [Chapter 16](#).

For upgrade requirements imposed by vanilla PostgreSQL, see [Section E.22](#).

E.12. Release 16.10

Release date: 2025-08-14

This release contains a variety of fixes from 16.9. For information about new features in major release 16, see [Section E.22](#).

E.12.1. Migration to Version 16.10

A dump/restore is not required for those running 16.X.

However, if you have any BRIN `numeric_minmax_multi_ops` indexes, it is advisable to reindex them after updating. See the fourth changelog entry below.

Also, if you are upgrading from a version earlier than 16.9, see [Section E.13](#).

E.12.2. Changes

- Tighten security checks in planner estimation functions (Dean Rasheed)

The fix for CVE-2017-7484, plus followup fixes, intended to prevent leaky functions from being applied to statistics data for columns that the calling user does not have permission to read. Two gaps in that protection have been found. One gap applies to partitioning and inheritance hierarchies where RLS policies on the tables should restrict access to statistics data, but did not.

The other gap applies to cases where the query accesses a table via a view, and the view owner has permissions to read the underlying table but the calling user does not have permissions on the view. The view owner's permissions satisfied the security checks, and the leaky function would get applied to the underlying table's statistics before we check the calling user's permissions on the view. This has been fixed by making security checks on views occur at the start of planning. That might cause permissions failures to occur earlier than before.

The PostgreSQL Project thanks Dean Rasheed for reporting this problem. (CVE-2025-8713)

- Prevent `pg_dump` scripts from being used to attack the user running the restore (Nathan Bossart)

Since dump/restore operations typically involve running SQL commands as superuser, the target database installation must trust the source server. However, it does not follow that the operating system user who executes `psql` to perform the restore should have to trust the source server. The risk here is that an attacker who has gained superuser-level control over the source server might be able to cause it to emit text that would be interpreted as `psql` meta-commands. That would pro-

vide shell-level access to the restoring user's own account, independently of access to the target database.

To provide a positive guarantee that this can't happen, extend `psql` with a `\restrict` command that prevents execution of further meta-commands, and teach `pg_dump` to issue that before any data coming from the source server.

The PostgreSQL Project thanks Martin Rakhmanov, Matthieu Denais, and RyotaK for reporting this problem. (CVE-2025-8714)

- Convert newlines to spaces in names included in comments in `pg_dump` output (Noah Misch)

Object names containing newlines offered the ability to inject arbitrary SQL commands into the output script. (Without the preceding fix, injection of `psql` meta-commands would also be possible this way.) CVE-2012-0868 fixed this class of problem at the time, but later work reintroduced several cases.

The PostgreSQL Project thanks Noah Misch for reporting this problem. (CVE-2025-8715)

- Fix incorrect distance calculation in BRIN `numeric_minmax_multi_ops` support function (Peter Eisentraut, Tom Lane)

The results were sometimes wrong on 64-bit platforms, and wildly wrong on 32-bit platforms. This did not produce obvious failures because the logic is only used to choose how to merge values into ranges; at worst the index would become inefficient and bloated. Nonetheless it's recommended to reindex any BRIN indexes that use the `numeric_minmax_multi_ops` operator class.

- Avoid regression in the size of XML input that we will accept (Michael Paquier, Erik Wienhold)

Our workaround for a bug in early 2.13.x releases of `libxml2` made use of a code path that rejects text chunks exceeding 10MB, whereas the previous coding did not. Those early releases are presumably extinct in the wild by now, so revert to the previous coding.

- Fix `MERGE` into a plain-inheritance parent table (Dean Rasheed)

Insertions into such a target table could crash or produce incorrect query results due to failing to handle `WITH CHECK OPTION` and `RETURNING` actions.

- Allow tables with statement-level triggers to become partitions or inheritance children (Etsuro Fujita)

We do not allow partitions or inheritance child tables to have row-level triggers with transition tables, because an operation on the whole inheritance tree would need to maintain a separate transition table for each such child table. But that problem does not apply for statement-level triggers, because only the parent's statement-level triggers will be fired. The code that checks whether an existing table can become a partition or inheritance child nonetheless rejected both kinds of trigger.

- Disallow collecting transition tuples from child foreign tables (Etsuro Fujita)

We do not support triggers with transition tables on foreign tables. However, the case of a partition or inheritance child that is a foreign table was overlooked. If the parent has such a trigger, incorrect transition tuples were collected from the foreign child. Instead throw an error, reporting that the case is not supported.

- Allow resetting unknown custom parameters with reserved prefixes (Nathan Bossart)

Previously, if a parameter setting had been stored using `ALTER DATABASE/ROLE/SYSTEM`, the stored setting could not be removed if the parameter was unknown but had a reserved prefix. This case could arise if an extension used to have a parameter, but that parameter had been removed in an upgrade.

- Fix a potential deadlock during `ALTER SUBSCRIPTION ... DROP PUBLICATION` (Ajin Cherian)

Ensure that server processes acquire catalog locks in a consistent order during replication origin drops.

- Shorten the race condition window for creating indexes with conflicting names (Tom Lane)

When choosing an auto-generated name for an index, avoid conflicting with not-yet-committed `pg_class` rows as well as fully-valid ones. This avoids possibly choosing the same name as some concurrent `CREATE INDEX` did, when that command is still in process of filling its index, or is done but is part of a not-yet-committed transaction. There's still a window for trouble, but it's only as long as the time needed to validate a new index's parameters and insert its `pg_class` row.

- Prevent usage of incorrect `VACUUM` options in some cases where multiple tables are vacuumed in a single command (Nathan Bossart, Michael Paquier)

The `TRUNCATE` and `INDEX_CLEANUP` options of one table could be applied to others.

- Fix processing of character classes within `SIMILAR TO` regular expressions (Laurenz Albe)

The code that translates `SIMILAR TO` pattern matching expressions to POSIX-style regular expressions did not consider that square brackets can be nested. For example, in a pattern like `[[:alpha:]]%_`, the code treated the `%` and `_` characters as metacharacters when they should be literals.

- When deparsing queries, always add parentheses around the expression in `FETCH FIRST expression ROWS WITH TIES` clauses (Heikki Linnakangas)

This avoids some cases where the deparsed result wasn't syntactically valid.

- Limit the checkpoint process's `fsync` request queue size (Alexander Korotkov, Xuneng Zhou)

With very large `shared_buffers` settings, it was possible for the checkpoint to attempt to allocate more than 1GB for `fsync` requests, leading to failure and an infinite loop. Clamp the queue size to prevent this scenario.

- Avoid infinite wait in logical decoding when reading a partially-written WAL record (Vignesh C)

If the server crashes after writing the first part of a WAL record that would span multiple pages, subsequent logical decoding of the WAL stream would wait for data to arrive on the next WAL page. That might never happen if the server is now idle.

- Fix inconsistent quoting of role names in ACL strings (Tom Lane)

The previous quoting rule was locale-sensitive, which could lead to portability problems when transferring `aclitem` values across installations. (`pg_dump` does not do that, but other tools might.) To ensure consistency, always quote non-ASCII characters in `aclitem` output; but to preserve backward compatibility, never require that they be quoted during `aclitem` input.

- Reject equal signs (=) in the names of relation options and foreign-data options (Tom Lane)

There's no evident use-case for option names like this, and allowing them creates ambiguity in the stored representation.

- Fix potentially-incorrect decompression of LZ4-compressed archive data (Mikhail Gribkov)

This error seems to manifest only with not-very-compressible input data, which may explain why it escaped detection.

- Avoid a rare scenario where a btree index scan could mark the wrong index entries as dead (Peter Geoghegan)
- Avoid re-distributing cache invalidation messages from other transactions during logical replication (vignesh C)

Our previous round of minor releases included a bug fix to ensure that replication receiver processes would respond to cross-process cache invalidation messages, preventing them from using stale

catalog data while performing replication updates. However, the fix unintentionally made them also redistribute those messages again, leading to an exponential increase in the number of invalidation messages, which would often end in a memory allocation failure. Fix by not redistributing received messages.

- Avoid premature removal of old WAL during checkpoints (Vitaly Davydov)

If a replication slot's restart point is advanced while a checkpoint is in progress, no-longer-needed WAL segments could get removed too soon, leading to recovery failure if the database crashes immediately afterwards. Fix by keeping them for one additional checkpoint cycle.

- Never move a replication slot's confirmed-flush position backwards (Shveta Malik)

In some cases a replication client could acknowledge an LSN that's past what it has stored persistently, and then perhaps send an older LSN after a restart. We consider this not-a-bug so long as the client did not have anything it needed to do for the WAL between the two points. However, we should not re-send that WAL for fear of data duplication, so make sure we always believe the latest confirmed LSN for a given slot.

- Prevent excessive delays before launching new logical replication workers (Tom Lane)

In some cases the logical replication launcher could sleep considerably longer than the configured `wal_retrieve_retry_interval` before launching a new worker.

- Fix use-after-free during logical replication of `INSERT ... ON CONFLICT` (Ethan Mertz, Michael Paquier)

This could result in incorrect progress reporting, or with very bad luck it could result in a crash of the WAL sender process.

- Allow waiting for a transaction on a standby server to be interrupted (Kevin K Biju)

Creation of a replication slot on a standby server may require waiting for some active transaction(s) to finish on the primary and then be replayed on the standby. Since that could be an indefinite wait, it's desirable to allow the operation to be cancelled, but there was no check for query cancel in the loop.

- Do not let cascading logical WAL senders try to send data that's beyond what has been replayed on their standby server (Alexey Makhmutov)

This avoids a situation where such WAL senders could get stuck at standby server shutdown, waiting for replay work that will not happen because the server's startup process is already shut down.

- Fix per-relation memory leakage in autovacuum (Tom Lane)
- Fix session-lifespan memory leaks in `XMLSERIALIZE(... INDENT)` (Dmitry Kovalenko, Tom Lane)
- Fix some places that might try to fetch toasted fields of system catalogs without any snapshot (Nathan Bossart)

This could result in an assertion failure or “cannot fetch toast data without an active snapshot” error.

- Avoid assertion failure during cross-table constraint updates (Tom Lane, Jian He)
- Remove faulty assertion that a command tag must have been determined by the end of `PortalRunMulti()` (Álvaro Herrera)

This failed in edge cases such as an empty prepared statement.

- Fix assertion failure in `XMLTABLE` parsing (Richard Guo)
- Restore the ability to run PL/pgSQL expressions in parallel (Dipesh Dhameliya)

PL/pgSQL's notion of an “expression” is very broad, encompassing any SQL `SELECT` query that returns a single column and no more than one row. So there are cases, for example evaluation of an

aggregate function, where the query involves significant work and it'd be useful to run it with parallel workers. This used to be possible, but a previous bug fix unintentionally disabled it.

- Fix edge-case resource leaks in PL/Python error reporting (Tom Lane)

An out-of-memory failure while reporting an error from Python could result in failure to drop reference counts on Python objects, leading to session-lifespan memory leakage.

- Fix libpq's `PQport()` function to never return NULL unless the passed connection is NULL (Daniele Varrazzo)

This is the documented behavior, but recent libpq versions would return NULL in some cases where the user had not provided a port specification. Revert to our historical behavior of returning an empty string in such cases. (v18 and later will return the compiled-in default port number, typically "5432", instead.)

- Avoid failure when GSSAPI authentication requires packets larger than 16kB (Jacob Champion, Tom Lane)

Larger authentication packets are needed for Active Directory users who belong to many AD groups. This limitation manifested in connection failures with unintelligible error messages, typically "GSSAPI context establishment error: The routine must be called again to complete its function: Unknown error".

- Fix timing-dependent failures in SSL and GSSAPI data transmission (Tom Lane)

When using SSL or GSSAPI encryption in non-blocking mode, libpq sometimes failed with "SSL error: bad length" or "GSSAPI caller failed to retransmit all data needing to be retried".

- Avoid null-pointer dereference during connection lookup in ecpg applications (Aleksander Alekseev)

The case could occur only if the application has some connections that are named and some that are not.

- Improve psql's tab completion for `COPY` and `\copy` options (Atsushi Torikoshi)

The same completions were offered for both `COPY FROM` and `COPY TO`, although some options are only valid for one case or the other. Distinguish these cases to provide more accurate suggestions.

- Avoid assertion failure in pgbench when multiple pipeline sync messages are received (Fujii Masao)
- Ensure that `pg_dump` dumps comments on domain constraints in a valid order (Jian He)

In some cases the comment command could appear before creation of the constraint.

- Ensure stable sort ordering in `pg_dump` for all types of database objects (Noah Misch, Andreas Karlsson)

`pg_dump` sorts objects by their logical names before performing dependency-driven reordering. This sort did not account for the full unique key identifying certain object types such as rules and constraints, and thus it could produce dissimilar sort orders for logically-identical databases. That made it difficult to compare databases by diff'ing `pg_dump` output, so improve the logic to ensure stable sort ordering in all cases.

- In `pg_upgrade`, check for inconsistent inherited not-null constraints (Ali Akbar)

PostgreSQL versions before 18 allow an inherited column not-null constraint to be dropped. However, this results in a schema that cannot be restored, leading to failure in `pg_upgrade`. Detect such cases during `pg_upgrade`'s preflight checks to allow users to fix them before initiating the upgrade.

- Avoid assertion failure if `track_commit_timestamp` is enabled during `initdb` (Hayato Kuroda, Andy Fan)
- Fix `pg_waldump` to show information about dropped statistics in `PREPARE TRANSACTION` WAL records (Daniil Davydov)

- Avoid possible leak of the open connection during `contrib/dblink` connection establishment (Tom Lane)

In the rare scenario where we hit out-of-memory while inserting the new connection object into `dblink`'s hashtable, the open connection would be leaked until end of session, leaving an idle session sitting on the remote server.

- Make `contrib/pg_prewarm` cope with very large `shared_buffers` settings (Daria Shanina)

Autoprewarm failed with a memory allocation error if `shared_buffers` was larger than about 50 million buffers (400GB).

- In `contrib/pg_stat_statements`, avoid leaving gaps in the set of parameter numbers used in a normalized query (Sami Imseih)
- Fix memory leakage in `contrib/postgres_fdw`'s `DirectModify` methods (Tom Lane)

The `PGresult` holding the results of the remote modify command would be leaked for the rest of the session if the query fails between invocations of the `DirectModify` methods, which could happen when there's `RETURNING` data to process.

- Ensure that directories listed in `configure`'s `--with-includes` and `--with-libraries` options are searched before system-supplied directories (Tom Lane)

A common reason for using these options is to allow a user-built version of some library to override the system-supplied version. However, that failed to work in some environments because of careless ordering of switches in the commands issued by the makefiles.

- Fix `configure`'s checks for `__cpuid()` and `__cpuidex()` (Lukas Fittl, Michael Paquier)

`configure` failed to detect these Windows-specific functions, so that they would not be used, leading to slower-than-necessary CRC computations since the availability of hardware instructions could not be verified. The practical impact of this error was limited, because production builds for Windows typically do not use the Autoconf toolchain.

- Fix build failure with `--with-pam` option on Solaris-based platforms (Tom Lane)

Solaris is inconsistent with other Unix platforms about the API for PAM authentication. This manifested as an “inconsistent pointer” compiler warning, which we never did anything about. But as of GCC 14 it's an error not warning by default, so fix it.

- Make our code portable to GNU Hurd (Michael Banck, Christoph Berg, Samuel Thibault)

Fix assumptions about `IOV_MAX` and `O_RDONLY` that don't hold on Hurd.

- Make our usage of `memset_s()` conform strictly to the C11 standard (Tom Lane)

This avoids compile failures on some platforms.

- Silence compatibility warning when using Meson to build with MSVC (Peter Eisentraut)
- Prevent uninitialized-value compiler warnings in JSONB comparison code (Tom Lane)
- Avoid deprecation warnings when building with libxml2 2.14 and later (Michael Paquier)
- Avoid problems when compiling `pg_locale.h` under C++ (John Naylor)

PostgreSQL header files generally need to be wrapped in `extern "C" { ... }` in order to be included in extensions written in C++. This failed for `pg_locale.h` because of its use of `libc` headers, but we can work around that by suppressing C++-only declarations in those headers. C++ extensions that want to use `libc`'s C++ APIs can do so by including the `libc` headers ahead of `pg_locale.h`.

E.13. Release 16.9

Release date: 2025-05-08

This release contains a variety of fixes from 16.8. For information about new features in major release 16, see [Section E.22](#).

E.13.1. Migration to Version 16.9

A dump/restore is not required for those running 16.X.

However, if you have any self-referential foreign key constraints on partitioned tables, it may be necessary to recreate those constraints to ensure that they are being enforced correctly. See the second changelog entry below.

Also, if you have any BRIN bloom indexes, it may be advisable to reindex them after updating. See the third changelog entry below.

Also, if you are upgrading from a version earlier than 16.5, see [Section E.17](#).

E.13.2. Changes

- Avoid one-byte buffer overread when examining invalidly-encoded strings that are claimed to be in GB18030 encoding (Noah Misch, Andres Freund)

While unlikely, a SIGSEGV crash could occur if an incomplete multibyte character appeared at the end of memory. This was possible both in the server and in libpq-using applications. (CVE-2025-4207)

- Handle self-referential foreign keys on partitioned tables correctly (Álvaro Herrera)

Creating or attaching partitions failed to make the required catalog entries for a foreign-key constraint, if the table referenced by the constraint was the same partitioned table. This resulted in failure to enforce the constraint fully.

To fix this, you should drop and recreate any self-referential foreign keys on partitioned tables, if partitions have been created or attached since the constraint was created. Bear in mind that violating rows might already be present, in which case recreating the constraint will fail, and you'll need to fix up those rows before trying again.

- Avoid data loss when merging compressed BRIN summaries in `brin_bloom_union()` (Tomas Vondra)

The code failed to account for decompression results not being identical to the input objects, which would result in failure to add some of the data to the merged summary, leading to missed rows in index searches.

This mistake was present back to v14 where BRIN bloom indexes were introduced, but this code path was only rarely reached then. It's substantially more likely to be hit in v17 because parallel index builds now use the code.

- Fix unexpected “attribute has wrong type” errors in `UPDATE`, `DELETE`, and `MERGE` queries that use whole-row table references to views or functions in `FROM` (Tom Lane)
- Fix `MERGE` into a partitioned table with `DO NOTHING` actions (Tender Wang)

Some cases failed with “unknown action in `MERGE WHEN` clause” errors.

- Prevent failure in `INSERT` commands when the table has a `GENERATED` column of a domain data type and the domain's constraints disallow null values (Jian He)

Constraint failure was reported even if the generation expression produced a perfectly okay result.

- Correctly process references to outer CTE names that appear within a `WITH` clause attached to an `INSERT/UPDATE/DELETE/MERGE` command that's inside `WITH` (Tom Lane)

The parser failed to detect disallowed recursion cases, nor did it account for such references when sorting CTEs into a usable order.

- Don't try to parallelize `array_agg()` when the argument is of an anonymous record type (Richard Guo, Tom Lane)

The protocol for communicating with parallel workers doesn't support identifying the concrete record type that a worker is returning.

- Fix `ARRAY(subquery)` and `ARRAY[expression, ...]` constructs to produce sane results when the input is of type `int2vector` or `oidvector` (Tom Lane)

This patch restores the behavior that existed before PostgreSQL 9.5: the result is of type `int2vector[]` or `oidvector[]`.

- Fix possible erroneous reports of invalid affixes while parsing Ispell dictionaries (Jacob Brazeal)
- Fix `ALTER TABLE ADD COLUMN` to correctly handle the case of a domain type that has a default (Jian He, Tom Lane, Tender Wang)

If a domain type has a default, adding a column of that type (without any explicit `DEFAULT` clause) failed to install the domain's default value in existing rows, instead leaving the new column null.

- Repair misbehavior when there are duplicate column names in a foreign key constraint's `ON DELETE SET DEFAULT` or `SET NULL` action (Tom Lane)
- Improve the error message for disallowed attempts to alter the properties of a foreign key constraint (Álvaro Herrera)
- Avoid error when resetting the `relhassubclass` flag of a temporary table that's marked `ON COMMIT DELETE ROWS` (Noah Misch)
- Add missing deparsing of the `INDENT` option of `XMLSERIALIZE()` (Jim Jones)

Previously, views or rules using `XMLSERIALIZE(... INDENT)` were dumped without the `INDENT` clause, causing incorrect results after restore.

- Avoid premature evaluation of the arguments of an aggregate function that has both `FILTER` and `ORDER BY` (or `DISTINCT`) options (David Rowley)

If there is `ORDER BY` or `DISTINCT`, we consider pre-sorting the aggregate input values rather than doing the sort within the Agg plan node. But this is problematic if the aggregate inputs include expressions that could fail (for example, a division where some of the input divisors could be zero) and there is a `FILTER` clause that's meant to prevent such failures. Pre-sorting would push the expression evaluations to before the `FILTER` test, allowing the failures to happen anyway. Avoid this by not pre-sorting if there's a `FILTER` and the input expressions are anything more complex than a simple Var or Const.

- Fix planner's failure to identify more than one hashable `ScalarArrayOpExpr` subexpression within a top-level expression (David Geier)

This resulted in unnecessarily-inefficient execution of any additional subexpressions that could have been processed with a hash table (that is, `IN`, `NOT IN`, or `= ANY` clauses with all-constant right-hand sides).

- Disable “skip fetch” optimization in bitmap heap scan (Matthias van de Meent)

It turns out that this optimization can result in returning dead tuples when a concurrent vacuum marks a page all-visible.

- Fix performance issues in GIN index search startup when there are many search keys (Tom Lane, Vinod Sridharan)

An indexable clause with many keys (for example, `jsonbcol ?| array[...]` with tens of thousands of array elements) took $O(N^2)$ time to start up, and was uncancelable for that interval too.

- Detect missing support procedures in a BRIN index operator class, and report an error instead of crashing (Álvaro Herrera)

- Respond to interrupts (such as query cancel) while waiting for asynchronous subplans of an Append plan node (Heikki Linnakangas)

Previously, nothing would happen until one of the subplans becomes ready.

- Report the I/O statistics of active WAL senders more frequently (Bertrand Drouvot)

Previously, the `pg_stat_io` view failed to accumulate I/O performed by a WAL sender until that process exited. Now such I/O will be reported after at most one second's delay.

- Fix race condition in handling of `synchronous_standby_names` immediately after startup (Melnikov Maksim, Michael Paquier)

For a short period after system startup, backends might fail to wait for synchronous commit even though `synchronous_standby_names` is enabled.

- Avoid infinite loop if `scram_iterations` is set to `INT_MAX` (Kevin K Biju)
- Avoid possible crashes due to double transformation of `json_array()`'s subquery (Tom Lane)
- Fix `pg_strtof()` to not crash with null `endptr` (Alexander Lakhin, Tom Lane)
- Fix crash after out-of-memory in certain GUC assignments (Daniel Gustafsson)
- Avoid crash when a Snowball stemmer encounters an out-of-memory condition (Maksim Korotkov)
- Disallow copying of invalidated replication slots (Shlok Kyal)

This prevents trouble when the invalid slot points to WAL that's already been removed.

- Disallow restoring logical replication slots on standby servers that are not in hot-standby mode (Masahiko Sawada)

This prevents a scenario where the slot could remain valid after promotion even if `wal_level` is too low.

- Prevent over-advancement of catalog xmin in “fast forward” mode of logical decoding (Zhijie Hou)

This mistake could allow deleted catalog entries to be vacuumed away even though they were still potentially needed by the WAL-reading process.

- Avoid data loss when DDL operations that don't take a strong lock affect tables that are being logically replicated (Shlok Kyal, Hayato Kuroda)

The catalog changes caused by the DDL command were not reflected into WAL-decoding processes, allowing them to decode subsequent changes using stale catalog data, probably resulting in data corruption.

- Prevent incorrect reset of replication origin when an apply worker encounters an error but the error is caught and does not result in worker exit (Hayato Kuroda)

This mistake could allow duplicate data to be applied.

- Avoid duplicate snapshot creation in logical replication index lookups (Heikki Linnakangas)
- Improve detection of mixed-origin subscriptions (Hou Zhijie, Shlok Kyal)

Subscription creation gives a warning if a subscribed-to table is also being followed through other publications, since that could cause duplicate data to be received. This change improves that logic to also detect cases where a partition parent or child table is the one being followed through another publication.

- Fix wrong checkpoint details in error message about incorrect recovery timeline choice (David Steele)

If the requested recovery timeline is not reachable, the reported checkpoint and timeline should be the values read from the `backup_label`, if there is one. This message previously reported values

from the control file, which is correct when recovering from the control file without a `backup_label`, but not when there is a `backup_label`.

- Remove incorrect assertion in `pgstat_report_stat()` (Michael Paquier)
- Fix overly-strict assertion in `gistFindCorrectParent()` (Heikki Linnakangas)
- Fix rare assertion failure in standby servers when the primary is restarted (Heikki Linnakangas)
- In PL/pgSQL, avoid “unexpected plan node type” error when a scrollable cursor is defined on a simple `SELECT expression` query (Andrei Lepikhov)
- Don't try to drop individual index partitions in `pg_dump`'s `--clean` mode (Jian He)

The server rejects such `DROP` commands. That has no real consequences, since the partitions will go away anyway in the subsequent `DROPS` of either their parent tables or their partitioned index. However, the error reported for the attempted drop causes problems when restoring in `--single-transaction` mode.

- In `pg_dumpall`, avoid emitting invalid role `GRANT` commands if `pg_auth_members` contains invalid role OIDs (Tom Lane)

Instead, print a warning and skip the entry. This copes better with catalog corruption that has been seen to occur in back branches as a result of race conditions between `GRANT` and `DROP ROLE`.

- In `pg_amcheck` and `pg_upgrade`, use the correct function to free allocations made by `libpq` (Michael Paquier, Ranier Vilela)

These oversights could result in crashes in certain Windows build configurations, such as a debug build of `libpq` used by a non-debug build of the calling application.

- Allow `contrib/dblink` queries to be interrupted by query cancel (Noah Misch)

This change back-patches a v17-era fix. It prevents possible hangs in `CREATE DATABASE` and `DROP DATABASE` due to failure to detect deadlocks.

- Avoid crashing with corrupt input data in `contrib/pageinspect`'s `heap_page_items()` (Dmitry Kovalenko)
- Prevent assertion failure in `contrib/pg_freespacemap`'s `pg_freespacemap()` (Tender Wang)

Applying `pg_freespacemap()` to a relation lacking storage (such as a view) caused an assertion failure, although there was no ill effect in non-assert builds. Add an error check to reject that case.

- Fix build failure on macOS 15.4 (Tom Lane, Peter Eisentraut)

This macOS update broke our configuration probe for `strchrnul()`.

- Update time zone data files to tzdata release 2025b for DST law changes in Chile, plus historical corrections for Iran (Tom Lane)

There is a new time zone `America/Coyhaique` for Chile's Aysén Region, to account for it changing to UTC-03 year-round and thus diverging from `America/Santiago`.

E.14. Release 16.8

Release date: 2025-02-20

This release contains a few fixes from 16.7. For information about new features in major release 16, see [Section E.22](#).

E.14.1. Migration to Version 16.8

A dump/restore is not required for those running 16.X.

However, if you are upgrading from a version earlier than 16.5, see [Section E.17](#).

E.14.2. Changes

- Improve behavior of `libpq`'s quoting functions (Andres Freund, Tom Lane)

The changes made for CVE-2025-1094 had one serious oversight: `PQescapeLiteral()` and `PQescapeIdentifier()` failed to honor their string length parameter, instead always reading to the input string's trailing null. This resulted in including unwanted text in the output, if the caller intended to truncate the string via the length parameter. With very bad luck it could cause a crash due to reading off the end of memory.

In addition, modify all these quoting functions so that when invalid encoding is detected, an invalid sequence is substituted for just the first byte of the presumed character, not all of it. This reduces the risk of problems if a calling application performs additional processing on the quoted string.

- Fix meson build system to correctly detect availability of the `bsd_auth.h` system header (Nazir Bilal Yavuz)

E.15. Release 16.7

Release date: 2025-02-13

This release contains a variety of fixes from 16.6. For information about new features in major release 16, see [Section E.22](#).

E.15.1. Migration to Version 16.7

A dump/restore is not required for those running 16.X.

However, if you are upgrading from a version earlier than 16.5, see [Section E.17](#).

E.15.2. Changes

- Harden `PQescapeString` and allied functions against invalidly-encoded input strings (Andres Freund, Noah Misch)

Data-quoting functions supplied by `libpq` now fully check the encoding validity of their input. If invalid characters are detected, they report an error if possible. For the ones that lack an error return convention, the output string is adjusted to ensure that the server will report invalid encoding and no intervening processing will be fooled by bytes that might happen to match single quote, backslash, etc.

The purpose of this change is to guard against SQL-injection attacks that are possible if one of these functions is used to quote crafted input. There is no hazard when the resulting string is sent directly to a PostgreSQL server (which would check its encoding anyway), but there is a risk when it is passed through `psql` or other client-side code. Historically such code has not carefully vetted encoding, and in many cases it's not clear what it should do if it did detect such a problem.

This fix is effective only if the data-quoting function, the server, and any intermediate processing agree on the character encoding that's being used. Applications that insert untrusted input into SQL commands should take special care to ensure that that's true.

Applications and drivers that quote untrusted input without using these `libpq` functions may be at risk of similar problems. They should first confirm the data is valid in the encoding expected by the server.

The PostgreSQL Project thanks Stephen Fewer for reporting this problem. (CVE-2025-1094)

- Exclude parallel workers from connection privilege checks and limits (Tom Lane)

Do not check `dataallowconn`, `rolcanlogin`, and `ACL_CONNECT` privileges when starting a parallel worker, instead assuming that it's enough for the leader process to have passed similar checks

originally. This avoids, for example, unexpected failures of parallelized queries when the leader is running as a role that lacks login privilege. In the same vein, enforce `ReservedConnections`, `datconnlimit`, and `rolconnlimit` limits only against regular backends, and count only regular backends while checking if the limits were already reached. Those limits are meant to prevent excessive consumption of process slots for regular backends --- but parallel workers and other special processes have their own pools of process slots with their own limit checks.

- Fix possible re-use of stale results in window aggregates (David Rowley)

A window aggregate with a “run condition” optimization and a pass-by-reference result type might incorrectly return the result from the previous partition instead of performing a fresh calculation.

- Keep `TransactionXmin` in sync with `MyProc->xmin` (Heikki Linnakangas)

This oversight could permit a process to try to access data that had already been vacuumed away. One known consequence is transient “could not access status of transaction” errors.

- Fix race condition that could cause failure to add a newly-inserted catalog entry to a catalog cache list (Heikki Linnakangas)

This could result, for example, in failure to use a newly-created function within an existing session.

- Prevent possible catalog corruption when a system catalog is vacuumed concurrently with an update (Noah Misch)
- Fix data corruption when relation truncation fails (Thomas Munro)

The filesystem calls needed to perform relation truncation could fail, leaving inconsistent state on disk (for example, effectively reviving deleted data). We can't really prevent that, but we can recover by dint of making such failures into PANICs, so that consistency is restored by replaying from WAL up to just before the attempted truncation. This isn't a hugely desirable behavior, but such failures are rare enough that it seems an acceptable solution.

- Prevent checkpoints from starting during relation truncation (Robert Haas)

This avoids a race condition wherein the modified file might not get `fsync`'d before completing the checkpoint, creating a risk of data corruption if the operating system crashes soon after.

- Avoid possibly losing an update of `pg_database.datfrozenxid` when `VACUUM` runs concurrently with a `REASSIGN OWNED` that changes that database's owner (Kirill Reshke)
- Fix incorrect `tg_updatedcols` values passed to `AFTER UPDATE` triggers (Tom Lane)

In some cases the `tg_updatedcols` bitmap could describe the set of columns updated by an earlier command in the same transaction, fooling the trigger into doing the wrong thing.

Also, prevent memory bloat caused by making too many copies of the `tg_updatedcols` bitmap.

- Fix detach of a partition that has its own foreign-key constraint referencing a partitioned table (Amul Sul)

In common cases, foreign keys are defined on a partitioned table's top level; but if instead one is defined on a partition and references a partitioned table, and the referencing partition is detached, the relevant `pg_constraint` entries were updated incorrectly. This led to errors like “could not find ON INSERT check triggers of foreign key constraint”.

- Fix mis-processing of `to_timestamp`'s `FFn` format codes (Tom Lane)

An integer format code immediately preceding `FFn` would consume all available digits, leaving none for `FFn`.

- When deparsing an `XMLTABLE()` expression, ensure that XML namespace names are double-quoted when necessary (Dean Rasheed)
- Include the `ldapscheme` option in `pg_hba_file_rules()` output (Laurenz Albe)

- Don't merge `UNION` operations if their column collations aren't consistent (Tom Lane)

Previously we ignored collations when deciding if it's safe to merge `UNION` steps into a single N-way `UNION` operation. This was arguably valid before the introduction of nondeterministic collations, but it's not anymore, since the collation in use can affect the definition of uniqueness.

- Prevent “wrong varnullingrels” planner errors after pulling up a subquery that's underneath an outer join (Tom Lane)
- Ignore nulling-relation marker bits when looking up statistics (Richard Guo)

This oversight could lead to failure to use relevant statistics about expressions, or to “corrupt MVNDDistinct entry” errors.

- Fix missed expression processing for partition pruning steps (Tom Lane)

This oversight could lead to “unrecognized node type” errors, and perhaps other problems, in queries accessing partitioned tables.

- Allow dhash tables to grow past 1GB (Matthias van de Meent)

This avoids errors like “invalid DSA memory alloc request size”. The case can occur for example in transactions that process several million tables.

- Avoid possible integer overflow in `bringetbitmap()` (James Hunter, Evgeniy Gorbanyov)

Since the result is only used for statistical purposes, the effects of this error were mostly cosmetic.

- Ensure that an already-set process latch doesn't prevent the postmaster from noticing socket events (Thomas Munro)

An extremely heavy workload of backends launching workers and workers exiting could prevent the postmaster from responding to incoming client connections in a timely fashion.

- Prevent streaming standby servers from looping infinitely when reading a WAL record that crosses pages (Kyotaro Horiguchi, Alexander Kukushkin)

This would happen when the record's continuation is on a page that needs to be read from a different WAL source.

- Fix unintended promotion of FATAL errors to PANIC during early process startup (Noah Misch)

This fixes some unlikely cases that would result in “PANIC: proc_exit() called in child process”.

- Fix cases where an operator family member operator or support procedure could become a dangling reference (Tom Lane)

In some cases a data type could be dropped while references to its OID still remain in `pg_amop` or `pg_amproc`. While that caused no immediate issues, an attempt to drop the owning operator family would fail, and `pg_dump` would produce bogus output when dumping the operator family. This fix causes creation and modification of operator families/classes to add needed dependency entries so that dropping a data type will also drop any dependent operator family elements. That does not help vulnerable pre-existing operator families, though, so a band-aid has also been added to `DROP OPERATOR FAMILY` to prevent failure when dropping a family that has dangling members.

- Fix multiple memory leaks in logical decoding output (Vignesh C, Masahiko Sawada, Boyu Yang)
- Fix small memory leak when updating the `application_name` or `cluster_name` settings (Tofig Aliev)
- Avoid integer overflow while testing `wal_skip_threshold` condition (Tom Lane)

A transaction that created a very large relation could mistakenly decide to ensure durability by copying the relation into WAL instead of fsync'ing it, thereby negating the point of `wal_skip_threshold`. (This only matters when `wal_level` is set to `minimal`, else a WAL copy is required anyway.)

- Fix unsafe order of operations during cache lookups (Noah Misch)

The only known consequence was a usually-harmless “you don't own a lock of type ExclusiveLock” warning during `GRANT TABLESPACE`.

- Fix possible “failed to resolve name” failures when using JIT on older ARM platforms (Thomas Munro)

This could occur as a consequence of inconsistency about the default setting of `-moutline-atomics` between gcc and clang. At least Debian and Ubuntu are known to ship gcc and clang compilers that target armv8-a but differ on the use of outline atomics by default.

- Fix assertion failure in `WITH RECURSIVE ... UNION` queries (David Rowley)
- Avoid assertion failure in rule deparsing if a set operation leaf query contains set operations (Man Zeng, Tom Lane)
- Avoid edge-case assertion failure in parallel query startup (Tom Lane)
- Fix assertion failure at shutdown when writing out the statistics file (Michael Paquier)
- In `NULLIF()`, avoid passing a read-write expanded object pointer to the data type's equality function (Tom Lane)

The equality function could modify or delete the object if it's given a read-write pointer, which would be bad if we decide to return it as the `NULLIF()` result. There is probably no problem with any built-in equality function, but it's easy to demonstrate a failure with one coded in PL/pgSQL.

- Ensure that expression preprocessing is applied to a default null value in `INSERT` (Tom Lane)

If the target column is of a domain type, the planner must insert a coerce-to-domain step not just a null constant, and this expression missed going through some required processing steps. There is no known consequence with domains based on core data types, but in theory an error could occur with domains based on extension types.

- Repair memory leaks in PL/Python (Mat Arye, Tom Lane)

Repeated use of `PLyPlan.execute` or `plpy.cursor` resulted in memory leakage for the duration of the calling PL/Python function.

- Fix PL/Tcl to compile with Tcl 9 (Peter Eisentraut)
- In the `ecpg` preprocessor, fix possible misprocessing of cursors that reference out-of-scope variables (Tom Lane)
- In `ecpg`, fix compile-time warnings about unsupported use of `COPY ... FROM STDIN` (Ryo Kanbayashi)

Previously, the intended warning was not issued due to a typo.

- Fix `psql` to safely handle file path names that are encoded in SJIS (Tom Lane)

Some two-byte characters in SJIS have a second byte that is equal to ASCII backslash (`\`). These characters were corrupted by path name normalization, preventing access to files whose names include such characters.

- Fix use of wrong version of `pqsignal()` in `pgbench` and `psql` (Fujii Masao, Tom Lane)

This error could lead to misbehavior when using the `-T` option in `pgbench` or the `\watch` command in `psql`, due to interrupted system calls not being resumed as expected.

- Fix misexecution of some nested `\if` constructs in `pgbench` (Michail Nikolaev)

An `\if` command appearing within a false (not-being-executed) `\if` branch was incorrectly treated the same as `\elif`.

- In `pgbench`, fix possible misdisplay of progress messages during table initialization (Yushi Ogiwara, Tatsuo Ishii, Fujii Masao)
- Make `pg_controldata` more robust against corrupted `pg_control` files (Ilyasov Ian, Anton Voloshin)

Since `pg_controldata` will attempt to print the contents of `pg_control` even if the CRC check fails, it must take care not to misbehave for invalid field values. This patch fixes some issues triggered by invalid timestamps and apparently-negative WAL segment sizes.

- Fix possible crash in `pg_dump` with identity sequences attached to tables that are extension members (Tom Lane)
- Fix memory leak in `pg_restore` with `zstd`-compressed data (Tom Lane)

The leak was per-decompression-operation, so would be most noticeable with a dump containing many tables or large objects.

- Fix `pg_basebackup` to correctly handle `pg_wal.tar` files exceeding 2GB on Windows (Davinder Singh, Thomas Munro)
- Use SQL-standard function bodies in the declarations of `contrib/earthdistance`'s SQL-language functions (Tom Lane, Ronan Dunklau)

This change allows their references to `contrib/cube` to be resolved during extension creation, reducing the risk of search-path-based failures and possible attacks.

In particular, this restores their usability in contexts like generated columns, for which PostgreSQL v17 restricts the search path on security grounds. We have received reports of databases failing to be upgraded to v17 because of that. This patch has been included in v16 to provide a workaround: updating the `earthdistance` extension to this version beforehand should allow an upgrade to succeed.

- Update configuration probes that determine the compiler switches needed to access ARM CRC instructions (Tom Lane)

On ARM platforms where the baseline CPU target lacks CRC instructions, we need to supply a `-march` switch to persuade the compiler to compile such instructions. Recent versions of `gcc` reject the value we were trying, leading to silently falling back to software CRC.

- Fix meson build system to support old OpenSSL libraries on Windows (Darek Slusarczyk)

Add support for the legacy library names `ssleay32` and `libeay32`.

- In Windows builds using meson, ensure all `libcommon` and `libpgport` functions are exported (Vladlen Popolitov, Heikki Linnakangas)

This fixes “unresolved external symbol” build errors for extensions.

- Fix meson configuration process to correctly detect OSSP's `uuid.h` header file under MSVC (Andrew Dunstan)
- When building with meson, install `pgevent` in `pkglibdir` not `bindir` (Peter Eisentraut)

This matches the behavior of the make-based build system and the old MSVC build system.

- When building with meson, install `sepgsql.sql` under `share/contrib/` not `share/extension/` (Peter Eisentraut)

This matches what the make-based build system does.

- Update time zone data files to `tzdata` release 2025a for DST law changes in Paraguay, plus historical corrections for the Philippines (Tom Lane)

E.16. Release 16.6

Release date: 2024-11-21

This release contains a few fixes from 16.5. For information about new features in major release 16, see [Section E.22](#).

E.16.1. Migration to Version 16.6

A dump/restore is not required for those running 16.X.

However, if you are upgrading from a version earlier than 16.5, see [Section E.17](#).

E.16.2. Changes

- Repair ABI break for extensions that work with struct `ResultRelInfo` (Tom Lane)

Last week's minor releases unintentionally broke binary compatibility with `timescaledb` and several other extensions. Restore the affected structure to its previous size, so that such extensions need not be rebuilt.

- Restore functionality of `ALTER {ROLE|DATABASE} SET role` (Tom Lane, Noah Misch)

The fix for CVE-2024-10978 accidentally caused settings for `role` to not be applied if they come from non-interactive sources, including previous `ALTER {ROLE|DATABASE}` commands and the `PGOPTIONS` environment variable.

- Fix cases where a logical replication slot's `restart_lsn` could go backwards (Masahiko Sawada)

Previously, restarting logical replication could sometimes cause the slot's restart point to be recomputed as an older value than had previously been advertised in `pg_replication_slots`. This is bad, since for example WAL files might have been removed on the basis of the later `restart_lsn` value, in which case replication would fail to restart.

- Avoid deleting still-needed WAL files during `pg_rewind` (Polina Bungina, Alexander Kukushkin)

Previously, in unlucky cases, it was possible for `pg_rewind` to remove important WAL files from the rewound demoted primary. In particular this happens if those files have been marked for archival (i.e., their `.ready` files were created) but not yet archived. Then the newly promoted node no longer has such files because of them having been recycled, but likely they are needed for recovery in the demoted node. If `pg_rewind` removes them, recovery is not possible anymore.

- Fix race conditions associated with dropping shared statistics entries (Kyotaro Horiguchi, Michael Paquier)

These bugs could lead to loss of statistics data, assertion failures, or “can only drop stats once” errors.

- Count index scans in `contrib/bloom` indexes in the statistics views, such as the `pg_stat_user_indexes.idx_scan` counter (Masahiro Ikeda)
- Fix crash when checking to see if an index's `opclass` options have changed (Alexander Korotkov)

Some forms of `ALTER TABLE` would fail if the table has an index with non-default operator class options.

- Avoid assertion failure caused by disconnected NFA sub-graphs in regular expression parsing (Tom Lane)

This bug does not appear to have any visible consequences in non-assert builds.

E.17. Release 16.5

Release date: 2024-11-14

This release contains a variety of fixes from 16.4. For information about new features in major release 16, see [Section E.22](#).

E.17.1. Migration to Version 16.5

A dump/restore is not required for those running 16.X.

However, if you have ever detached a partition from a partitioned table that has a foreign-key reference to another partitioned table, and not dropped the former partition, then you may have catalog and/or data corruption to repair, as detailed in the fifth changelog entry below.

Also, if you are upgrading from a version earlier than 16.3, see [Section E.19](#).

E.17.2. Changes

- Ensure cached plans are marked as dependent on the calling role when RLS applies to a non-top-level table reference (Nathan Bossart)

If a CTE, subquery, sublink, security invoker view, or coercion projection in a query references a table with row-level security policies, we neglected to mark the resulting plan as potentially dependent on which role is executing it. This could lead to later query executions in the same session using the wrong plan, and then returning or hiding rows that should have been hidden or returned instead.

The PostgreSQL Project thanks Wolfgang Walther for reporting this problem. (CVE-2024-10976)

- Make libpq discard error messages received during SSL or GSS protocol negotiation (Jacob Champion)

An error message received before encryption negotiation is completed might have been injected by a man-in-the-middle, rather than being real server output. Reporting it opens the door to various security hazards; for example, the message might spoof a query result that a careless user could mistake for correct output. The best answer seems to be to discard such data and rely only on libpq's own report of the connection failure.

The PostgreSQL Project thanks Jacob Champion for reporting this problem. (CVE-2024-10977)

- Fix unintended interactions between `SET SESSION AUTHORIZATION` and `SET ROLE` (Tom Lane)

The SQL standard mandates that `SET SESSION AUTHORIZATION` have a side-effect of doing `SET ROLE NONE`. Our implementation of that was flawed, creating more interaction between the two settings than intended. Notably, rolling back a transaction that had done `SET SESSION AUTHORIZATION` would revert `ROLE` to `NONE` even if that had not been the previous state, so that the effective user ID might now be different from what it had been before the transaction. Transiently setting `session_authorization` in a function `SET` clause had a similar effect. A related bug was that if a parallel worker inspected `current_setting('role')`, it saw `none` even when it should see something else.

The PostgreSQL Project thanks Tom Lane for reporting this problem. (CVE-2024-10978)

- Prevent trusted PL/Perl code from changing environment variables (Andrew Dunstan, Noah Misch)

The ability to manipulate process environment variables such as `PATH` gives an attacker opportunities to execute arbitrary code. Therefore, “trusted” PLs must not offer the ability to do that. To fix `plperl`, replace `%ENV` with a tied hash that rejects any modification attempt with a warning. Untrusted `plperl_u` retains the ability to change the environment.

The PostgreSQL Project thanks Coby Abrams for reporting this problem. (CVE-2024-10979)

- Fix updates of catalog state for foreign-key constraints when attaching or detaching table partitions (Jehan-Guillaume de Rorthais, Tender Wang, Álvaro Herrera)

If the referenced table is partitioned, then different catalog entries are needed for a referencing table that is stand-alone versus one that is a partition. `ATTACH/DETACH PARTITION` commands failed to perform this conversion correctly. In particular, after `DETACH` the now stand-alone table would be

missing foreign-key enforcement triggers, which could result in the table later containing rows that fail the foreign-key constraint. A subsequent `re-ATTACH` could fail with surprising errors, too.

The way to fix this is to do `ALTER TABLE DROP CONSTRAINT` on the now stand-alone table for each faulty constraint, and then re-add the constraint. If re-adding the constraint fails, then some erroneous data has crept in. You will need to manually re-establish consistency between the referencing and referenced tables, then re-add the constraint.

This query can be used to identify broken constraints and construct the commands needed to recreate them:

```
SELECT conrelid::pg_catalog.regclass AS "constrained table",
       conname AS constraint,
       confrelid::pg_catalog.regclass AS "references",
       pg_catalog.format('ALTER TABLE %s DROP CONSTRAINT %I;',
                        conrelid::pg_catalog.regclass, conname) AS "drop",
       pg_catalog.format('ALTER TABLE %s ADD CONSTRAINT %I %s;',
                        conrelid::pg_catalog.regclass, conname,
                        pg_catalog.pg_get_constraintdef(oid)) AS "add"
FROM pg_catalog.pg_constraint c
WHERE contype = 'f' AND conparentid = 0 AND
      ((SELECT count(*) FROM pg_catalog.pg_constraint c2
        WHERE c2.conparentid = c.oid) <>
      ((SELECT count(*) FROM pg_catalog.pg_inherits i
        WHERE (i.inhparent = c.conrelid OR i.inhparent = c.confrelid) AND
              EXISTS (SELECT 1 FROM pg_catalog.pg_partitioned_table
                      WHERE partrelid = i.inhparent)) +
      CASE WHEN pg_catalog.pg_partition_root(conrelid) = confrelid THEN
        (SELECT count(*) FROM pg_catalog.pg_partition_tree(confrelid)
         WHERE level = 1)
      ELSE 0 END);
```

Since it is possible that one or more of the `ADD CONSTRAINT` steps will fail, you should save the query's output in a file and then attempt to perform each step.

- Avoid possible crashes and “could not open relation” errors in queries on a partitioned table occurring concurrently with a `DETACH CONCURRENTLY` and immediate drop of a partition (Álvaro Herrera, Kuntal Gosh)
- Disallow `ALTER TABLE ATTACH PARTITION` if the table to be attached has a foreign key referencing the partitioned table (Álvaro Herrera)

This arrangement is not supported, and other ways of creating it already fail.

- Don't use partitionwise joins or grouping if the query's collation for the key column doesn't match the partition key's collation (Jian He, Webbo Han)

Such plans could produce incorrect results.

- Fix possible “could not find pathkey item to sort” error when the output of a `UNION ALL` member query needs to be sorted, and the sort column is an expression (Andrei Lepikhov, Tom Lane)
- Fix performance regressions involving flattening of subqueries underneath outer joins that are later reduced to plain joins (Tom Lane)

v16 failed to optimize some queries as well as prior versions had, because of overoptimistic simplification of query-pullup logic.

- Allow cancellation of the second stage of index build for large hash indexes (Pavel Borisov)
- Fix assertion failure or confusing error message for `COPY (query) TO ...`, when the *query* is rewritten by a `DO INSTEAD NOTIFY` rule (Tender Wang, Tom Lane)
- Fix server crash when a `json_objectagg()` call contains a volatile function (Amit Langote)

- Fix checking of key uniqueness in JSON object constructors (Junwang Zhao, Tomas Vondra)

When building an object larger than a kilobyte, it was possible to accept invalid input that includes duplicate object keys, or to falsely report that duplicate keys are present.

- Fix detection of skewed data during parallel hash join (Thomas Munro)

After repartitioning the inner side of a hash join because one partition has accumulated too many tuples, we check to see if all the partition's tuples went into the same child partition, which suggests that they all have the same hash value and further repartitioning cannot improve matters. This check malfunctioned in some cases, allowing repeated futile repartitioning which would eventually end in a resource-exhaustion error.

- Disallow locale names containing non-ASCII characters (Thomas Munro)

This is only an issue on Windows, as such locale names are not used elsewhere. They are problematic because it's quite unclear what encoding such names are represented in (since the locale itself defines the encoding to use). In recent PostgreSQL releases, an abort in the Windows runtime library could occur because of confusion about that.

Anyone who encounters the new error message should either create a new duplicated locale with an ASCII-only name using Windows Locale Builder, or consider using BCP 47-compliant locale names like `tr-TR`.

- Fix race condition in committing a serializable transaction (Heikki Linnakangas)

Mis-processing of a recently committed transaction could lead to an assertion failure or a “could not access status of transaction” error.

- Fix race condition in `COMMIT PREPARED` that resulted in orphaned 2PC files (wuchengwen)

A concurrent `PREPARE TRANSACTION` could cause `COMMIT PREPARED` to not remove the on-disk two-phase state file for the completed transaction. There was no immediate ill effect, but a subsequent crash-and-recovery could fail with “could not access status of transaction”, requiring manual removal of the orphaned file to restore service.

- Avoid invalid memory accesses after skipping an invalid toast index during `VACUUM FULL` (Tender Wang)

A list tracking yet-to-be-rebuilt indexes was not properly updated in this code path, risking assertion failures or crashes later on.

- Fix ways in which an “in place” catalog update could be lost (Noah Misch)

Normal row updates write a new version of the row to preserve rollback-ability of the transaction. However, certain system catalog updates are intentionally non-transactional and are done with an in-place update of the row. These patches fix race conditions that could cause the effects of an in-place update to be lost. As an example, it was possible to forget having set `pg_class.relhasindex` to true, preventing updates of the new index and thus causing index corruption.

- Reset catalog caches at end of recovery (Noah Misch)

This prevents scenarios wherein an in-place catalog update could be lost due to using stale data from a catalog cache.

- Avoid using parallel query while holding off interrupts (Francesco Degrossi, Noah Misch, Tom Lane)

This situation cannot arise normally, but it can be reached with test scenarios such as using a SQL-language function as B-tree support (which would be far too slow for production usage). If it did occur it would result in an indefinite wait.

- Report the active query ID for statistics purposes at the start of processing of Bind and Execute protocol messages (Sami Imseih)

This allows more of the work done in extended query protocol to be attributed to the correct query.

- Guard against stack overflow in libxml2 with too-deeply-nested XML input (Tom Lane, with hat tip to Nick Wellnhofer)

Use `xmlXPathCtxtCompile()` rather than `xmlXPathCompile()`, because the latter fails to protect itself against recursion-to-stack-overflow in libxml2 releases before 2.13.4.

- Fix some whitespace issues in the result of `XMLSERIALIZE(... INDENT)` (Jim Jones)

Fix failure to indent nodes separated by whitespace, and ensure that a trailing newline is not added.

- Do not ignore a concurrent `REINDEX CONCURRENTLY` that is working on an index with predicates or expressions (Michail Nikolaev)

Normally, `REINDEX CONCURRENTLY` does not need to wait for other `REINDEX CONCURRENTLY` operations on other tables. However, this optimization is not applied if the other `REINDEX CONCURRENTLY` is processing an index with predicates or expressions, on the chance that such expressions contain user-defined code that accesses other tables. Careless coding created a race condition such that that rule was not applied uniformly, possibly allowing inconsistent behavior.

- Fix mis-deparsing of `ORDER BY` lists when there is a name conflict (Tom Lane)

If an `ORDER BY` item in `SELECT` is a bare identifier, the parser first seeks it as an output column name of the `SELECT`, for SQL92 compatibility. However, `ruleutils.c` expects the SQL99 interpretation where such a name is an input column name. So it was possible to produce an incorrect display of a view in the (rather ill-advised) case where some other column is renamed in the `SELECT` output list to match an input column used in `ORDER BY`. Fix by table-qualifying such names in the dumped view text.

- Fix “failed to find plan for subquery/CTE” errors in `EXPLAIN` (Richard Guo, Tom Lane)

This case arose while trying to print references to fields of a `RECORD`-type output of a subquery when the subquery has been optimized out of the plan altogether (which is possible at least in the case that it has a constant-false `WHERE` condition). Nothing remains in the plan to identify the original field names, so fall back to printing `fN` for the *N*'th record column. (That's actually the right thing anyway, if the record output arose from a `ROW()` constructor.)

- Disallow a `USING` clause when altering the type of a generated column (Peter Eisentraut)

A generated column already has an expression specifying the column contents, so including `USING` doesn't make sense.

- Ignore not-yet-defined Portals in the `pg_cursors` view (Tom Lane)

It is possible for user-defined code that inspects this view to be called while a new cursor is being set up, and if that happens a null pointer dereference would ensue. Avoid the problem by defining the view to exclude incompletely-set-up cursors.

- Fix incorrect output of the `pg_stat_io` view on 32-bit machines (Bertrand Drouvot)

The `stats_reset` timestamp column contained garbage on such hardware.

- Prevent mis-encoding of “trailing junk after numeric literal” error messages (Karina Litskevich)

We do not allow identifiers to appear immediately following numeric literals (there must be some whitespace between). If a multibyte character immediately followed a numeric literal, the syntax error message about it included only the first byte of that character, causing bad-encoding problems both in the report to the client and in the postmaster log file.

- Avoid “unexpected `table_index_fetch_tuple` call during logical decoding” error while decoding a transaction involving insertion of a column default value (Takeshi Ideriha, Hou Zhijie)

- Reduce memory consumption of logical decoding (Masahiko Sawada)

Use a smaller default block size to store tuple data received during logical replication. This reduces memory wastage, which has been reported to be severe while processing long-running transactions, even leading to out-of-memory failures.

- In a logical replication apply worker, ensure that origin progress is not advanced during an error or apply worker shutdown (Hayato Kuroda, Shveta Malik)

This avoids possible loss of a transaction, since once the origin progress point is advanced the source server won't send that data again.

- Re-disable sending of stateless (TLSv1.2) session tickets (Daniel Gustafsson)

A previous change to prevent sending of stateful (TLSv1.3) session tickets accidentally re-enabled sending of stateless ones. Thus, while we intended to prevent clients from thinking that TLS session resumption is supported, some still did.

- Avoid “wrong tuple length” failure when dropping a database with many ACL (permission) entries (Ayush Tiwari)
- Allow adjusting the `session_authorization` and `role` settings in parallel workers (Tom Lane)

Our code intends to allow modifiable server settings to be set by function `SET` clauses, but not otherwise within a parallel worker. `SET` clauses failed for these two settings, though.

- Fix behavior of stable functions called from a `CALL` statement's argument list, when the `CALL` is within a PL/pgSQL `EXCEPTION` block (Tom Lane)

As with a similar fix in our previous quarterly releases, this case allowed such functions to be passed the wrong snapshot, causing them to see stale values of rows modified since the start of the outer transaction.

- Fix “cache lookup failed for function” errors in edge cases in PL/pgSQL's `CALL` (Tom Lane)
- Fix thread safety of our fallback (non-OpenSSL) MD5 implementation on big-endian hardware (Heikki Linnakangas)

Thread safety is not currently a concern in the server, but it is for libpq.

- Parse libpq's `keepalives` connection option in the same way as other integer-valued options (Yuto Sasaki)

The coding used here rejected trailing whitespace in the option value, unlike other cases. This turns out to be problematic in `ecpg`'s usage, for example.

- Avoid use of `pnstrdup()` in `ecpglib` (Jacob Champion)

That function will call `exit()` on out-of-memory, which is undesirable in a library. The calling code already handles allocation failures properly.

- In `ecpglib`, fix out-of-bounds read when parsing incorrect datetime input (Bruce Momjian, Pavel Nekrasov)

It was possible to try to read the location just before the start of a constant array. Real-world consequences seem minimal, though.

- Fix memory leak in `psql` during repeated use of `\bind` (Michael Paquier)
- Avoid hanging if an interval less than 1ms is specified in `psql`'s `\watch` command (Andrey Borodin, Michael Paquier)

Instead, treat this the same as an interval of zero (no wait between executions).

- Fix `pg_dump`'s handling of identity sequences that have persistence different from their owning table's persistence (Tom Lane)

Since v15, it's been possible to set an identity sequence to be LOGGED when its owning table is UNLOGGED or vice versa. However, `pg_dump`'s method for recreating that situation failed in binary-upgrade mode, causing `pg_upgrade` to fail when such sequences are present. Fix by introducing a new option for `ADD/ALTER COLUMN GENERATED AS IDENTITY` to allow the sequence's persistence to be set correctly at creation. Note that this means a dump from a database containing such a sequence will only load into a server of this minor version or newer.

- Include the source timeline history in `pg_rewind`'s debug output (Heikki Linnakangas)

This was the intention to begin with, but a coding error caused the source history to always print as empty.

- Avoid trying to reindex temporary tables and indexes in `vacuumdb` and in parallel `reindexdb` (VaibhaveS, Michael Paquier, Fujii Masao, Nathan Bossart)

Reindexing other sessions' temporary tables cannot work, but the check to skip them was missing in some code paths, leading to unwanted failures.

- Allow inspection of sequence relations in relevant functions of `contrib/pageinspect` and `contrib/pgstattuple` (Nathan Bossart, Ayush Vatsa)

This had been allowed in the past, but it got broken during the introduction of non-default access methods for tables.

- Fix incorrect LLVM-generated code on ARM64 platforms (Thomas Munro, Anthonin Bonnefoy)

When using JIT compilation on ARM platforms, the generated code could not support relocation distances exceeding 32 bits, allowing unlucky placement of generated code to cause server crashes on large-memory systems.

- Fix a few places that assumed that process start time (represented as a `time_t`) will fit into a `long` value (Max Johnson, Nathan Bossart)

On platforms where `long` is 32 bits (notably Windows), this coding would fail after Y2038. Most of the failures appear only cosmetic, but notably `pg_ctl start` would hang.

- Fix building with Strawberry Perl on Windows (Andrew Dunstan)
- Update time zone data files to tzdata release 2024b (Tom Lane)

This tzdata release changes the old System-V-compatibility zone names to duplicate the corresponding geographic zones; for example `PST8PDT` is now an alias for `America/Los_Angeles`. The main visible consequence is that for timestamps before the introduction of standardized time zones, the zone is considered to represent local mean solar time for the named location. For example, in `PST8PDT`, `timestampz` input such as `1801-01-01 00:00` would previously have been rendered as `1801-01-01 00:00:00-08`, but now it is rendered as `1801-01-01 00:00:00-07:52:58`.

Also, historical corrections for Mexico, Mongolia, and Portugal. Notably, `Asia/Choibalsan` is now an alias for `Asia/Ulaanbaatar` rather than being a separate zone, mainly because the differences between those zones were found to be based on untrustworthy data.

E.18. Release 16.4

Release date: 2024-08-08

This release contains a variety of fixes from 16.3. For information about new features in major release 16, see [Section E.22](#).

E.18.1. Migration to Version 16.4

A dump/restore is not required for those running 16.X.

However, if you are upgrading from a version earlier than 16.3, see [Section E.19](#).

E.18.2. Changes

- Prevent unauthorized code execution during `pg_dump` (Masahiko Sawada)

An attacker able to create and drop non-temporary objects could inject SQL code that would be executed by a concurrent `pg_dump` session with the privileges of the role running `pg_dump` (which is often a superuser). The attack involves replacing a sequence or similar object with a view or foreign table that will execute malicious code. To prevent this, introduce a new server parameter `restrict_nonsystem_relation_kind` that can disable expansion of non-builtin views as well as access to foreign tables, and teach `pg_dump` to set it when available. Note that the attack is prevented only if both `pg_dump` and the server it is dumping from are new enough to have this fix.

The PostgreSQL Project thanks Noah Misch for reporting this problem. (CVE-2024-7348)

- Avoid incorrect results from Merge Right Anti Join plans (Richard Guo)

If the inner relation is known to have unique join keys, the merge could misbehave when there are duplicated join keys in the outer relation.

- Prevent infinite loop in `VACUUM` (Melanie Plageman)

After a disconnected standby server with an old running transaction reconnected to the primary, it was possible for `VACUUM` on the primary to get confused about which tuples are removable, resulting in an infinite loop.

- Fix failure after attaching a table as a partition, if the table had previously had inheritance children (Álvaro Herrera)
- Fix `ALTER TABLE DETACH PARTITION` for cases involving inconsistent index-based constraints (Álvaro Herrera, Tender Wang)

When a partitioned table has an index that is not associated with a constraint, but a partition has an equivalent index that is, then detaching the partition would misbehave, leaving the ex-partition's constraint with an incorrect `coninhcount` value. This would cause trouble during any further manipulations of that constraint.

- Fix partition pruning setup during `ALTER TABLE DETACH PARTITION CONCURRENTLY` (Álvaro Herrera)

The executor assumed that no partition could be detached between planning and execution of a query on a partitioned table. This is no longer true since the introduction of `DETACH PARTITION'S CONCURRENTLY` option, making it possible for query execution to fail transiently when that is used.

- Correctly update a partitioned table's `pg_class.reltuples` field to zero after its last child partition is dropped (Noah Misch)

The first `ANALYZE` on such a partitioned table must update `relhassubclass` as well, and that caused the `reltuples` update to be lost.

- Fix handling of polymorphic output arguments for procedures (Tom Lane)

The SQL `CALL` statement did not resolve the correct data types for such arguments, leading to errors such as “cannot display a value of type anyelement”, or even outright crashes. (But `CALL` in PL/pgSQL worked correctly.)

- Fix behavior of stable functions called from a `CALL` statement's argument list (Tom Lane)

If the `CALL` is within an atomic context (e.g. there's an outer transaction block), such functions were passed the wrong snapshot, causing them to see stale values of rows modified since the start of the outer transaction.

- Fix input of ISO-8601 “extended” time format for types `time` and `timetz` (Tom Lane)

Re-allow cases such as `T12:34:56`.

- Detect integer overflow in `money` calculations (Joseph Koshakow)

None of the arithmetic functions for the `money` type checked for overflow before, so they would silently give wrong answers for overflowing cases.

- Fix over-aggressive clamping of the scale argument in `round(numeric)` and `trunc(numeric)` (Dean Rasheed)

These functions clamped their scale argument to ± 2000 , but there are valid use-cases for it to be larger; the functions returned incorrect results in such cases. Instead clamp to the actual allowed range of type `numeric`.

- Fix result for `pg_size_pretty()` when applied to the smallest possible `bigint` value (Joseph Koshakow)
- Prevent `pg_sequence_last_value()` from failing on unlogged sequences on standby servers and on temporary sequences of other sessions (Nathan Bossart)

Make it return `NULL` in these cases instead of throwing an error.

- Fix parsing of ignored operators in `websearch_to_tsquery()` (Tom Lane)

Per the manual, punctuation in the input of `websearch_to_tsquery()` is ignored except for the special cases of dashes and quotes. However, parentheses and a few other characters appearing immediately before an `or` could cause `or` to be treated as a data word, rather than as an `OR` operator as expected.

- Detect another integer overflow case while computing new array dimensions (Joseph Koshakow)

Reject applying array dimensions `[-2147483648:2147483647]` to an empty array. This is closely related to CVE-2023-5869, but appears harmless since the array still ends up empty.

- Fix unportable usage of `strnxfm()` (Jeff Davis)

Some code paths for non-deterministic collations could fail with errors like “`pg_strnxfm()` returned unexpected result”.

- Detect another case of a new catalog cache entry becoming stale while detoasting its fields (Noah Misch)

An in-place update occurring while we expand out-of-line fields in a catalog tuple could be missed, leading to a catalog cache entry that lacks the in-place change but is not known to be stale. This is only possible in the `pg_database` catalog, so the effects are narrow, but misbehavior is possible.

- Correctly check updatability of view columns targeted by `INSERT ... DEFAULT` (Tom Lane)

If such a column is non-updatable, we should give an error reporting that. But the check was missed and then later code would report an unhelpful error such as “attribute number *N* not found in view targetlist”.

- Avoid reporting an unhelpful internal error for incorrect recursive queries (Tom Lane)

Rearrange the order of error checks so that we throw an on-point error when a `WITH RECURSIVE` query does not have a self-reference within the second arm of the `UNION`, but does have one self-reference in some other place such as `ORDER BY`.

- Lock owned sequences during `ALTER TABLE SET LOGGED|UNLOGGED` (Noah Misch)

These commands change the persistence of a table's owned sequences along with the table, but they failed to acquire lock on the sequences while doing so. This could result in losing the effects of concurrent `nextval()` calls.

- Don't throw an error if a queued `AFTER` trigger no longer exists (Tom Lane)

It's possible for a transaction to execute an operation that queues a deferred `AFTER` trigger for later execution, and then to drop the trigger before that happens. Formerly this led to weird errors such as "could not find trigger `NNNN`". It seems better to silently do nothing if the trigger no longer exists at the time when it would have been executed.

- Fix failure to remove `pg_init_privs` entries for column-level privileges when their table is dropped (Tom Lane)

If an extension grants some column-level privileges on a table it creates, relevant catalog entries would remain behind after the extension is dropped. This was harmless until/unless the table's OID was re-used for another relation, when it could interfere with what `pg_dump` dumps for that relation.

- Fix selection of an arbiter index for `ON CONFLICT` when the desired index has expressions or predicates (Tom Lane)

If a query using `ON CONFLICT` accesses the target table through an updatable view, it could fail with "there is no unique or exclusion constraint matching the `ON CONFLICT` specification", even though a matching index does exist.

- Refuse to modify a temporary table of another session with `ALTER TABLE` (Tom Lane)

Permissions checks normally would prevent this case from arising, but it is possible to reach it by altering a parent table whose child is another session's temporary table. Throw an error if we discover that such a child table belongs to another session.

- Fix handling of extended statistics on expressions in `CREATE TABLE LIKE STATISTICS` (Tom Lane)

The `CREATE` command failed to adjust column references in statistics expressions to the possibly-different column numbering of the new table. This resulted in invalid statistics objects that would cause problems later. A typical scenario where renumbering columns is needed is when the source table contains some dropped columns.

- Fix failure to recalculate sub-queries generated from `MIN()` or `MAX()` aggregates (Tom Lane)

In some cases the aggregate result computed at one row of the outer query could be re-used for later rows when it should not be. This has only been seen to happen when the outer query uses `DISTINCT` that is implemented with hash aggregation, but other cases may exist.

- Re-forbid underscore in positional parameters (Erik Wienhold)

As of v16 we allow integer literals to contain underscores. This change caused input such as `$1_234` to be taken as a single token, but it did not work correctly. It seems better to revert to the original definition in which a parameter symbol is only `$` followed by digits.

- Avoid crashing when a JIT-inlined backend function throws an error (Tom Lane)

The error state can include pointers into the dynamically loaded module holding the JIT-compiled code (for error location strings). In some code paths the module could get unloaded before the error report is processed, leading to `SIGSEGV` when the location strings are accessed.

- Cope with behavioral changes in libxml2 version 2.13.x (Erik Wienhold, Tom Lane)

Notably, we now suppress "chunk is not well balanced" errors from libxml2, unless that is the only reported error. This is to make error reports consistent between 2.13.x and earlier libxml2 versions. In earlier versions, that message was almost always redundant or outright incorrect, so 2.13.x substantially reduced the number of cases in which it's reported.

- Fix handling of subtransactions of prepared transactions when starting a hot standby server (Heikki Linnakangas)

When starting a standby's replay at a shutdown checkpoint WAL record, transactions that had been prepared but not yet committed on the primary are correctly understood as being still in

progress. But subtransactions of a prepared transaction (created by savepoints or PL/pgSQL exception blocks) were not accounted for and would be treated as aborted. That led to inconsistency if the prepared transaction was later committed.

- Prevent incorrect initialization of logical replication slots (Masahiko Sawada)

In some cases a replication slot's start point within the WAL stream could be set to a point within a transaction, leading to assertion failures or incorrect decoding results.

- Avoid “can only drop stats once” error during replication slot creation and drop (Floris Van Nee)
- Fix resource leakage in logical replication WAL sender (Hou Zhijie)

The walsender process leaked memory when publishing changes to a partitioned table whose partitions have row types physically different from the partitioned table's.

- Avoid memory leakage after servicing a notify or sinval interrupt (Tom Lane)

The processing functions for these events could switch the current memory context to TopMemoryContext, resulting in session-lifespan leakage of any data allocated before the incorrect setting gets replaced. There were observable leaks associated with (at least) encoding conversion of incoming queries and parameters attached to Bind messages.

- Prevent leakage of reference counts for the shared memory block used for statistics (Anthonin Bonnetoy)

A new backend process attaching to the statistics shared memory incremented its reference count, but failed to decrement the count when exiting. After 2^{32} sessions had been created, the reference count would overflow to zero, causing failures in all subsequent backend process starts.

- Prevent deadlocks and assertion failures during truncation of the multixact SLRU log (Heikki Linakangas)

A process trying to delete SLRU segments could deadlock with the checkpointer process.

- Avoid possibly missing end-of-input events on Windows sockets (Thomas Munro)

Windows reports an FD_CLOSE event only once after the remote end of the connection disconnects. With unlucky timing, we could miss that report and wait indefinitely, or at least until a timeout elapsed, expecting more input.

- Fix buffer overread in JSON parse error reports for incomplete byte sequences (Jacob Champion)

It was possible to walk off the end of the input buffer by a few bytes when the last bytes comprise an incomplete multi-byte character. While usually harmless, in principle this could cause a crash.

- Disable creation of stateful TLS session tickets by OpenSSL (Daniel Gustafsson)

This avoids possible failures with clients that think receipt of a session ticket means that TLS session resumption is supported.

- When replanning a PL/pgSQL “simple expression”, check it's still simple (Tom Lane)

Certain fairly-artificial cases, such as dropping a referenced function and recreating it as an aggregate, could lead to surprising failures such as “unexpected plan node type”.

- Fix PL/pgSQL's handling of integer ranges containing underscores (Erik Wienhold)

As of v16 we allow integer literals to contain underscores, but PL/pgSQL failed to handle examples such as `FOR i IN 1_001..1_003`.

- Fix recursive RECORD-returning PL/Python functions (Tom Lane)

If we recurse to a new call of the same function that passes a different column definition list (AS clause), it would fail because the inner call would overwrite the outer call's idea of what rowtype to return.

- Don't corrupt PL/Python's `TD` dictionary during a recursive trigger call (Tom Lane)

If a PL/Python-language trigger caused another one to be invoked, the `TD` dictionary created for the inner one would overwrite the outer one's `TD` dictionary.

- Fix PL/Tcl's reporting of invalid list syntax in the result of a function returning tuple (Erik Wienhold, Tom Lane)

Such a case could result in a crash, or in emission of misleading context information that actually refers to the previous Tcl error.

- Avoid non-thread-safe usage of `strerror()` in `libpq` (Peter Eisentraut)

Certain error messages returned by OpenSSL could become garbled in multi-threaded applications.

- Avoid memory leak within `pg_dump` during a binary upgrade (Daniel Gustafsson)
- Ensure that `pg_restore -l` reports dependent TOC entries correctly (Tom Lane)

If `-l` was specified together with selective-restore options such as `-n` or `-N`, dependent TOC entries such as comments would be omitted from the listing, even when an actual restore would have selected them.

- Allow `contrib/pg_stat_statements` to distinguish among utility statements appearing within SQL-language functions (Anthonin Bonnefoy)

The SQL-language function executor failed to pass along the query ID that is computed for a utility (non `SELECT/INSERT/UPDATE/DELETE/MERGE`) statement.

- Avoid “cursor can only scan forward” error in `contrib/postgres_fdw` (Etsuro Fujita)

This error could occur if the remote server is v15 or later and a foreign table is mapped to a non-trivial remote view.

- In `contrib/postgres_fdw`, do not send `FETCH FIRST WITH TIES` clauses to the remote server (Japin Li)

The remote server might not implement this clause, or might interpret it differently than we would locally, so don't risk attempting remote execution.

- Avoid clashing with system-provided `<regex.h>` headers (Thomas Munro)

This fixes a compilation failure on macOS version 15 and up.

- Fix otherwise-harmless assertion failure in Memoize cost estimation (David Rowley)
- Fix otherwise-harmless assertion failures in `REINDEX CONCURRENTLY` applied to an SP-GiST index (Tom Lane)

E.19. Release 16.3

Release date: 2024-05-09

This release contains a variety of fixes from 16.2. For information about new features in major release 16, see [Section E.22](#).

E.19.1. Migration to Version 16.3

A dump/restore is not required for those running 16.X.

However, a security vulnerability was found in the system views `pg_stats_ext` and `pg_stats_ext_exprs`, potentially allowing authenticated database users to see data they shouldn't. If this is of concern in your installation, follow the steps in the first changelog entry below to rectify it.

Also, if you are upgrading from a version earlier than 16.2, see [Section E.20](#).

E.19.2. Changes

- Restrict visibility of `pg_stats_ext` and `pg_stats_ext_exprs` entries to the table owner (Nathan Bossart)

These views failed to hide statistics for expressions that involve columns the accessing user does not have permission to read. View columns such as `most_common_vals` might expose security-relevant data. The potential interactions here are not fully clear, so in the interest of erring on the side of safety, make rows in these views visible only to the owner of the associated table.

The PostgreSQL Project thanks Lukas Fittl for reporting this problem. (CVE-2024-4317)

By itself, this fix will only fix the behavior in newly initdb'd database clusters. If you wish to apply this change in an existing cluster, you will need to do the following:

1. Find the SQL script `fix-CVE-2024-4317.sql` in the `share` directory of the PostgreSQL installation (typically located someplace like `/usr/share/postgresql/`). Be sure to use the script appropriate to your PostgreSQL major version. If you do not see this file, either your version is not vulnerable (only v14-v16 are affected) or your minor version is too old to have the fix.
2. In *each* database of the cluster, run the `fix-CVE-2024-4317.sql` script as superuser. In `psql` this would look like

```
\i /usr/share/postgresql/fix-CVE-2024-4317.sql
```

(adjust the file path as appropriate). Any error probably indicates that you've used the wrong script version. It will not hurt to run the script more than once.

3. Do not forget to include the `template0` and `template1` databases, or the vulnerability will still exist in databases you create later. To fix `template0`, you'll need to temporarily make it accept connections. Do that with

```
ALTER DATABASE template0 WITH ALLOW_CONNECTIONS true;
```

and then after fixing `template0`, undo it with

```
ALTER DATABASE template0 WITH ALLOW_CONNECTIONS false;
```

- Fix `INSERT` from multiple `VALUES` rows into a target column that is a domain over an array or composite type (Tom Lane)

Such cases would either fail with surprising complaints about mismatched datatypes, or insert unexpected coercions that could lead to odd results.

- Require `SELECT` privilege on the target table for `MERGE` with a `DO NOTHING` clause (Álvaro Herrera)

`SELECT` privilege would be required in all practical cases anyway, but require it even if the query reads no columns of the target table. This avoids an edge case in which `MERGE` would require no privileges whatever, which seems undesirable even when it's a do-nothing command.

- Fix handling of self-modified tuples in `MERGE` (Dean Rasheed)

Throw an error if a target row joins to more than one source row, as required by the SQL standard. (The previous coding could silently ignore this condition if a concurrent update was involved.) Also, throw a non-misleading error if a target row is already updated by a later command in the current transaction, thanks to a `BEFORE` trigger or a volatile function used in the query.

- Fix incorrect pruning of `NULL` partition when a table is partitioned on a boolean column and the query has a boolean `IS NOT` clause (David Rowley)

A `NULL` value satisfies a clause such as `boolcol IS NOT FALSE`, so pruning away a partition containing `NULL`s yielded incorrect answers.

- Make `ALTER FOREIGN TABLE SET SCHEMA` move any owned sequences into the new schema (Tom Lane)

Moving a regular table to a new schema causes any sequences owned by the table to be moved to that schema too (along with indexes and constraints). This was overlooked for foreign tables, however.

- Make `ALTER TABLE ... ADD COLUMN` create identity/serial sequences with the same persistence as their owning tables (Peter Eisentraut)

`CREATE UNLOGGED TABLE` will make any owned sequences be unlogged too. `ALTER TABLE` missed that consideration, so that an added identity column would have a logged sequence, which seems pointless.

- Improve `ALTER TABLE ... ALTER COLUMN TYPE`'s error message when there is a dependent function or publication (Tom Lane)
- In `CREATE DATABASE`, recognize strategy keywords case-insensitively for consistency with other options (Tomas Vondra)
- Fix `EXPLAIN`'s counting of heap pages accessed by a bitmap heap scan (Melanie Plageman)

Previously, heap pages that contain no visible tuples were not counted; but it seems more consistent to count all pages returned by the bitmap index scan.

- Fix `EXPLAIN`'s output for subplans in `MERGE` (Dean Rasheed)

`EXPLAIN` would sometimes fail to properly display subplan Params referencing variables in other parts of the plan tree.

- Avoid deadlock during removal of orphaned temporary tables (Mikhail Zhilin)

If the session that creates a temporary table crashes without removing the table, autovacuum will eventually try to remove the orphaned table. However, an incoming session that's been assigned the same temporary namespace will do that too. If a temporary table has a dependency (such as an owned sequence) then a deadlock could result between these two cleanup attempts.

- Fix updating of visibility map state in `VACUUM` with the `DISABLE_PAGE_SKIPPING` option (Heikki Lin-nakangas)

Due to an oversight, this mode caused all heap pages to be dirtied, resulting in excess I/O. Also, visibility map bits that were incorrectly set would not get cleared.

- Avoid race condition while examining per-relation frozen-XID values (Noah Misch)

`VACUUM`'s computation of per-database frozen-XID values from per-relation values could get confused by a concurrent update of those values by another `VACUUM`.

- Fix buffer usage reporting for parallel vacuuming (Anthonin Bonnefoy)

Buffer accesses performed by parallel workers were not getting counted in the statistics reported in `VERBOSE` mode.

- Ensure that join conditions generated from equivalence classes are applied at the correct plan level (Tom Lane)

In versions before PostgreSQL 16, it was possible for generated conditions to be evaluated below outer joins when they should be evaluated above (after) the outer join, leading to incorrect query results. All versions have a similar hazard when considering joins to `UNION ALL` trees that have constant outputs for the join column in some `SELECT` arms.

- Fix “could not find pathkey item to sort” errors occurring while planning aggregate functions with `ORDER BY` or `DISTINCT` options (David Rowley)

This is similar to a fix applied in 16.1, but it solves the problem for parallel plans.

- Prevent potentially-incorrect optimization of some window functions (David Rowley)

Disable “run condition” optimization of `ntile()` and `count()` with non-constant arguments. This avoids possible misbehavior with sub-selects, typically leading to errors like “WindowFunc not found in subplan target lists”.

- Avoid unnecessary use of moving-aggregate mode with a non-moving window frame (Vallimaharan G)

When a plain aggregate is used as a window function, and the window frame start is specified as `UNBOUNDED PRECEDING`, the frame's head cannot move so we do not need to use the special (and more expensive) moving-aggregate mode. This optimization was intended all along, but due to a coding error it never triggered.

- Avoid use of already-freed data while planning partition-wise joins under GEQO (Tom Lane)

This would typically end in a crash or unexpected error message.

- Avoid freeing still-in-use data in Memoize (Tender Wang, Andrei Lepikhov)

In production builds this error frequently didn't cause any problems, as the freed data would most likely not get overwritten before it was used.

- Fix incorrectly-reported statistics kind codes in “requested statistics kind x is not yet built” error messages (David Rowley)
- Use a hash table instead of linear search for “catcache list” objects (Tom Lane)

This change solves performance problems that were reported for certain operations in installations with many thousands of roles.

- Be more careful with `RECORD`-returning functions in `FROM` (Tom Lane)

The output columns of such a function call must be defined by an `AS` clause that specifies the column names and data types. If the actual function output value doesn't match that, an error is supposed to be thrown at runtime. However, some code paths would examine the actual value prematurely, and potentially issue strange errors or suffer assertion failures if it doesn't match expectations.

- Fix confusion about the return rowtype of SQL-language procedures (Tom Lane)

A procedure implemented in SQL language that returns a single composite-type column would cause an assertion failure or core dump.

- Add protective stack depth checks to some recursive functions (Egor Chindyaskin)
- Fix mis-rounding and overflow hazards in `date_bin()` (Moaaz Assali)

In the case where the source timestamp is before the origin timestamp and their difference is already an exact multiple of the stride, the code incorrectly subtracted the stride anyway. Also, detect some integer-overflow cases that would have produced incorrect results.

- Detect integer overflow when adding or subtracting an `interval` to/from a `timestamp` (Joseph Koshakow)

Some cases that should cause an out-of-range error produced an incorrect result instead.

- Avoid race condition in `pg_get_expr()` (Tom Lane)

If the relation referenced by the argument is dropped concurrently, the function's intention is to return `NULL`, but sometimes it failed instead.

- Fix detection of old transaction IDs in `XID` status functions (Karina Litskevich)

Transaction IDs more than 2^{31} transactions in the past could be misidentified as recent, leading to misbehavior of `pg_xact_status()` or `txid_status()`.

- Ensure that a table's freespace map won't return a page that's past the end of the table (Ronan Dunklau)

Because the freespace map isn't WAL-logged, this was possible in edge cases involving an OS crash, a replica promote, or a PITR restore. The result would be a “could not read block” error.

- Fix file descriptor leakage when an error is thrown while waiting in `WaitEventSetWait` (Etsuro Fujita)
- Avoid corrupting exception stack if an FDW implements async append but doesn't configure any wait conditions for the Append plan node to wait for (Alexander Pyhalov)
- Throw an error if an index is accessed while it is being reindexed (Tom Lane)

Previously this was just an assertion check, but promote it into a regular runtime error. This will provide a more on-point error message when reindexing a user-defined index expression that attempts to access its own table.

- Ensure that index-only scans on `name` columns return a fully-padded value (David Rowley)

The value physically stored in the index is truncated, and previously a pointer to that value was returned to callers. This provoked complaints when testing under valgrind. In theory it could result in crashes, though none have been reported.

- Fix race condition that could lead to reporting an incorrect conflict cause when invalidating a replication slot (Bertrand Drouvot)
- Fix race condition in deciding whether a table sync operation is needed in logical replication (Vignesh C)

An invalidation event arriving while a subscriber identifies which tables need to be synced would be forgotten about, so that any tables newly in need of syncing might not get processed in a timely fashion.

- Fix crash with DSM allocations larger than 4GB (Heikki Linnakangas)
- Disconnect if a new server session's client socket cannot be put into non-blocking mode (Heikki Linnakangas)

It was once theoretically possible for us to operate with a socket that's in blocking mode; but that hasn't worked fully in a long time, so fail at connection start rather than misbehave later.

- Fix inadequate error reporting with OpenSSL 3.0.0 and later (Heikki Linnakangas, Tom Lane)

System-reported errors passed through by OpenSSL were reported with a numeric error code rather than anything readable.

- Fix thread-safety of error reporting for `getaddrinfo()` on Windows (Thomas Munro)

A multi-threaded libpq client program could get an incorrect or corrupted error message after a network lookup failure.

- Avoid concurrent calls to `bindtextdomain()` in libpq and ecpglib (Tom Lane)

Although GNU gettext's implementation seems to be fine with concurrent calls, the version available on Windows is not.

- Fix crash in ecpg's preprocessor if the program tries to redefine a macro that was defined on the preprocessor command line (Tom Lane)
- In ecpg, avoid issuing false “unsupported feature will be passed to server” warnings (Tom Lane)
- Ensure that the string result of ecpg's `intoasc()` function is correctly zero-terminated (Oleg Tselbrovskiy)
- In initdb's `-c` option, match parameter names case-insensitively (Tom Lane)

The server treats parameter names case-insensitively, so this code should too. This avoids putting redundant entries into the generated `postgresql.conf` file.

- In `psql`, avoid leaking a query result after the query is cancelled (Tom Lane)

This happened only when cancelling a non-last query in a query string made with `\;` separators.

- Fix `pg_dumpall` so that role comments, if present, will be dumped regardless of the setting of `--no-role-passwords` (Daniel Gustafsson, Álvaro Herrera)
- Skip files named `.DS_Store` in `pg_basebackup`, `pg_checksums`, and `pg_rewind` (Daniel Gustafsson)

This avoids problems on macOS, where the Finder may create such files.

- Fix PL/pgSQL's parsing of single-line comments (`---` style comments) following expressions (Erik Wienhold, Tom Lane)

This mistake caused parse errors if such a comment followed a `WHEN` expression in a PL/pgSQL `CASE` statement.

- In `contrib/amcheck`, don't report false match failures due to short- versus long-header values (Andrey Borodin, Michael Zhilin)

A variable-length datum in a heap tuple or index tuple could have either a short or a long header, depending on compression parameters that applied when it was made. Treat these cases as equivalent rather than complaining if there's a difference.

- Fix bugs in BRIN output functions (Tomas Vondra)

These output functions are only used for displaying index entries in `contrib/pageinspect`, so the errors are of limited practical concern.

- In `contrib/postgres_fdw`, avoid emitting requests to sort by a constant (David Rowley)

This could occur in cases involving `UNION ALL` with constant-emitting subqueries. Sorting by a constant is useless of course, but it also risks being misinterpreted by the remote server, leading to “ORDER BY position *N* is not in select list” errors.

- Make `contrib/postgres_fdw` set the remote session's time zone to GMT not UTC (Tom Lane)

This should have the same results for practical purposes. However, GMT is recognized by hard-wired code in the server, while UTC is looked up in the timezone database. So the old code could fail in the unlikely event that the remote server's timezone database is missing entries.

- In `contrib/xml2`, avoid use of library functions that have been deprecated in recent versions of libxml2 (Dmitry Koval)
- Fix incompatibility with LLVM 18 (Thomas Munro, Dmitry Dolgov)
- Allow `make check` to work with the musl C library (Thomas Munro, Bruce Momjian, Tom Lane)

E.20. Release 16.2

Release date: 2024-02-08

This release contains a variety of fixes from 16.1. For information about new features in major release 16, see [Section E.22](#).

E.20.1. Migration to Version 16.2

A dump/restore is not required for those running 16.X.

However, one bug was fixed that could have resulted in corruption of GIN indexes during concurrent updates. If you suspect such corruption, reindex affected indexes after installing this update.

Also, if you are upgrading from a version earlier than 16.1, see [Section E.21](#).

E.20.2. Changes

- Tighten security restrictions within `REFRESH MATERIALIZED VIEW CONCURRENTLY` (Heikki Linnakangas)

One step of a concurrent refresh command was run under weak security restrictions. If a materialized view's owner could persuade a superuser or other high-privileged user to perform a concurrent refresh on that view, the view's owner could control code executed with the privileges of the user running `REFRESH`. Fix things so that all user-determined code is run as the view's owner, as expected.

The only known exploit for this error does not work in PostgreSQL 16.0 and later, so it may be that v16 is not vulnerable in practice.

The PostgreSQL Project thanks Pedro Gallegos for reporting this problem. (CVE-2024-0985)

- Fix memory leak when performing JIT inlining (Andres Freund, Daniel Gustafsson)

There have been multiple reports of backend processes suffering out-of-memory conditions after sufficiently many JIT compilations. This fix should resolve that.

- Avoid generating incorrect partitioned-join plans (Richard Guo)

Some uncommon situations involving lateral references could create incorrect plans. Affected queries could produce wrong answers, or odd failures such as “variable not found in subplan target list”, or executor crashes.

- Fix incorrect wrapping of subquery output expressions in PlaceholderVars (Tom Lane)

This fixes incorrect results when a subquery is underneath an outer join and has an output column that laterally references something outside the outer join's scope. The output column might not appear as NULL when it should do so due to the action of the outer join.

- Fix misprocessing of window function run conditions (Richard Guo)

This oversight could lead to “WindowFunc not found in subplan target lists” errors.

- Fix detection of inner-side uniqueness for Memoize plans (Richard Guo)

This mistake could lead to “cache entry already complete” errors.

- Fix computation of nullingrels when constant-folding field selection (Richard Guo)

Failure to do this led to errors like “wrong varnullingrels (b) (expected (b 3)) for Var 2/2”.

- Skip inappropriate actions when `MERGE` causes a cross-partition update (Dean Rasheed)

When executing a `MERGE UPDATE` action on a partitioned table, if the `UPDATE` is turned into a `DELETE` and `INSERT` due to changing a partition key column, skip firing `AFTER UPDATE ROW` triggers, as well as other post-update actions such as RLS checks. These actions would typically fail, which is why a regular `UPDATE` doesn't do them in such cases; `MERGE` shouldn't either.

- Cope with `BEFORE ROW DELETE` triggers in cross-partition `MERGE` updates (Dean Rasheed)

If such a trigger attempted to prevent the update by returning NULL, `MERGE` would suffer an error or assertion failure.

- Prevent access to a no-longer-pinned buffer in `BEFORE ROW UPDATE` triggers (Alexander Lakhin, Tom Lane)

If the tuple being updated had just been updated and moved to another page by another session, there was a narrow window where we would attempt to fetch data from the new tuple version with-

out any pin on its buffer. In principle this could result in garbage data appearing in non-updated columns of the proposed new tuple. The odds of problems in practice seem rather low, however.

- Avoid requesting an oversize shared-memory area in parallel hash join (Thomas Munro, Andrei Lepikhov, Alexander Korotkov)

The limiting value was too large, allowing “invalid DSA memory alloc request size” errors to occur with sufficiently large expected hash table sizes.

- Fix corruption of local buffer state when an error occurs while trying to extend a temporary table (Tender Wang)
- Fix use of wrong tuple slot while evaluating `DISTINCT` aggregates that have multiple arguments (David Rowley)

This mistake could lead to errors such as “attribute 1 of type record has wrong type”.

- Avoid assertion failures in `heap_update()` and `heap_delete()` when a tuple to be updated by a foreign-key enforcement trigger fails the extra visibility crosscheck (Alexander Lakhin)

This error had no impact in non-assert builds.

- Fix overly tight assertion about `false_positive_rate` parameter of BRIN bloom operator classes (Alexander Lakhin)

This error had no impact in non-assert builds, either.

- Fix possible failure during `ALTER TABLE ADD COLUMN` on a complex inheritance tree (Tender Wang)

If a grandchild table would inherit the new column via multiple intermediate parents, the command failed with “tuple already updated by self”.

- Fix problems with duplicate token names in `ALTER TEXT SEARCH CONFIGURATION ... MAPPING` commands (Tender Wang, Michael Paquier)
- Fix `DROP ROLE` with duplicate role names (Michael Paquier)

Previously this led to a “tuple already updated by self” failure. Instead, ignore the duplicate.

- Properly lock the associated table during `DROP STATISTICS` (Tomas Vondra)

Failure to acquire the lock could result in “tuple concurrently deleted” errors if the `DROP` executes concurrently with `ANALYZE`.

- Fix function volatility checking for `GENERATED` and `DEFAULT` expressions (Tom Lane)

These places could fail to detect insertion of a volatile function default-argument expression, or decide that a polymorphic function is volatile although it is actually immutable on the datatype of interest. This could lead to improperly rejecting or accepting a `GENERATED` clause, or to mistakenly applying the constant-default-value optimization in `ALTER TABLE ADD COLUMN`.

- Detect that a new catalog cache entry became stale while detoasting its fields (Tom Lane)

We expand any out-of-line fields in a catalog tuple before inserting it into the catalog caches. That involves database access which might cause invalidation of catalog cache entries — but the new entry isn't in the cache yet, so we would miss noticing that it should get invalidated. The result is a race condition in which an already-stale cache entry could get made, and then persist indefinitely. This would lead to hard-to-predict misbehavior. Fix by rechecking the tuple's visibility after detoasting.

- Fix edge-case integer overflow detection bug on some platforms (Dean Rasheed)

Computing `0 - INT64_MIN` should result in an overflow error, and did on most platforms. However, platforms with neither integer overflow builtins nor 128-bit integers would fail to spot the overflow, instead returning `INT64_MIN`.

- Detect Julian-date overflow when adding or subtracting an `interval` to/from a `timestamp` (Tom Lane)

Some cases that should cause an out-of-range error produced an incorrect result instead.

- Add more checks for overflow in `interval_mul()` and `interval_div()` (Dean Rasheed)

Some cases that should cause an out-of-range error produced an incorrect result instead.

- Allow `scram_SaltedPassword()` to be interrupted (Bowen Shi)

With large `scram_iterations` values, this function could take a long time to run. Allow it to be interrupted by query cancel requests.

- Ensure cached statistics are discarded after a change to `stats_fetch_consistency` (Shinya Kato)

In some code paths, it was possible for stale statistics to be returned.

- Make the `pg_file_settings` view check validity of unapplied values for settings with `backend` or `superuser-backend` context (Tom Lane)

Invalid values were not noted in the view as intended. This escaped detection because there are very few settings in these groups.

- Match collation too when matching an existing index to a new partitioned index (Peter Eisentraut)

Previously we could accept an index that has a different collation from the corresponding element of the partition key, possibly leading to misbehavior.

- Avoid failure if a child index is dropped concurrently with `REINDEX INDEX` on a partitioned index (Fei Changhong)
- Fix insufficient locking when cleaning up an incomplete split of a GIN index's internal page (Fei Changhong, Heikki Linnakangas)

The code tried to do this with shared rather than exclusive lock on the buffer. This could lead to index corruption if two processes attempted the cleanup concurrently.

- Avoid premature release of buffer pin in GIN index insertion (Tom Lane)

If an index root page split occurs concurrently with our own insertion, the code could fail with “buffer NNNN is not owned by resource owner”.

- Avoid failure with partitioned SP-GiST indexes (Tom Lane)

Trying to use an index of this kind could lead to “No such file or directory” errors.

- Fix ownership tests for large objects (Tom Lane)

Operations on large objects that require ownership privilege failed with “unrecognized class ID: 2613”, unless run by a superuser.

- Fix ownership change reporting for large objects (Tom Lane)

A no-op `ALTER LARGE OBJECT OWNER` command (that is, one selecting the existing owner) passed the wrong class ID to the `PostAlterHook`, probably confusing any extension using that hook.

- Fix reporting of I/O timing data in `EXPLAIN (BUFFERS)` (Michael Paquier)

The numbers labeled as “shared/local” actually refer only to shared buffers, so change that label to “shared”.

- Ensure durability of `CREATE DATABASE` (Noah Misch)

If an operating system crash occurred during or shortly after `CREATE DATABASE`, recovery could fail, or subsequent connections to the new database could fail. If a base backup was taken in that win-

dow, similar problems could be observed when trying to use the backup. The symptom would be that the database directory, `PG_VERSION` file, or `pg_filenode.map` file was missing or empty.

- Add more `LOG` messages when starting and ending recovery from a backup (Andres Freund)

This change provides additional information in the postmaster log that may be useful for diagnosing recovery problems.

- Prevent standby servers from incorrectly processing dead index tuples during subtransactions (Fei Changhong)

The `startedInRecovery` flag was not correctly set for a subtransaction. This affects only processing of dead index tuples. It could allow a query in a subtransaction to ignore index entries that it should return (if they are already dead on the primary server, but not dead to the standby transaction), or to prematurely mark index entries as dead that are not yet dead on the primary. It is not clear that the latter case has any serious consequences, but it's not the intended behavior.

- Fix signal handling in walreceiver processes (Heikki Linnakangas)

Revert a change that made walreceivers non-responsive to `SIGTERM` while waiting for the replication connection to be established.

- Fix integer overflow hazard in checking whether a record will fit into the WAL decoding buffer (Thomas Munro)

This bug appears to be only latent except when running a 32-bit PostgreSQL build on a 64-bit platform.

- Fix deadlock between a logical replication apply worker, its tablesync worker, and a session process trying to alter the subscription (Shlok Kyal)

One edge of the deadlock loop did not involve a lock wait, so the deadlock went undetected and would persist until manual intervention.

- Ensure that column default values are correctly transmitted by the `pgoutput` logical replication plugin (Nikhil Benesch)

`ALTER TABLE ADD COLUMN` with a constant default value for the new column avoids rewriting existing tuples, instead expecting that reading code will insert the correct default into a tuple that lacks that column. If replication was subsequently initiated on the table, `pgoutput` would transmit `NULL` instead of the correct default for such a column, causing incorrect replication on the subscriber.

- Fix failure of logical replication's initial sync for a table with no columns (Vignesh C)

This case generated an improperly-formatted `COPY` command.

- Re-validate a subscription's connection string before use (Vignesh C)

This is meant to detect cases where a subscription was created without a password (which is allowed to superusers) but then the subscription owner is changed to a non-superuser.

- Return the correct status code when a new client disconnects without responding to the server's password challenge (Liu Lang, Tom Lane)

In some cases we'd treat this as a loggable error, which was not the intention and tends to create log spam, since common clients like `psql` frequently do this. It may also confuse extensions that use `ClientAuthentication_hook`.

- Fix incompatibility with OpenSSL 3.2 (Tristan Partin, Bo Andreson)

Use the `BIO "app_data"` field for our private storage, instead of assuming it's okay to use the `"data"` field. This mistake didn't cause problems before, but with 3.2 it leads to crashes and complaints about double frees.

- Be more wary about OpenSSL not setting `errno` on error (Tom Lane)

If `errno` isn't set, assume the cause of the reported failure is read EOF. This fixes rare cases of strange error reports like “could not accept SSL connection: Success”.

- Fix file descriptor leakage when a foreign data wrapper's `ForeignAsyncRequest` function fails (Heikki Linnakangas)
- Fix minor memory leak in connection string validation for `CREATE SUBSCRIPTION` (Jeff Davis)
- Report `ENOMEM` errors from file-related system calls as `ERRCODE_OUT_OF_MEMORY`, not `ERRCODE_INTERNAL_ERROR` (Alexander Kuzmenkov)
- In PL/pgSQL, support SQL commands that are `CREATE FUNCTION`/`CREATE PROCEDURE` with SQL-standard bodies (Tom Lane)

Previously, such cases failed with parsing errors due to the semicolon(s) appearing in the function body.

- Fix libpq's handling of errors in pipelines (Álvaro Herrera)

The pipeline state could get out of sync if an error is returned for reasons other than a query problem (for example, if the connection is lost). Potentially this would lead to a busy-loop in the calling application.

- Make libpq's `PQsendFlushRequest()` function flush the client output buffer under the same rules as other `PQsend` functions (Jelte Fennema-Nio)

In pipeline mode, it may still be necessary to call `PQflush()` as well; but this change removes some inconsistency.

- Avoid race condition when libpq initializes OpenSSL support concurrently in two different threads (Willi Mann, Michael Paquier)
- Fix timing-dependent failure in GSSAPI data transmission (Tom Lane)

When using GSSAPI encryption in non-blocking mode, libpq sometimes failed with “GSSAPI caller failed to retransmit all data needing to be retried”.

- Change `initdb` to always un-comment the `postgresql.conf` entries for the `lc_XXX` parameters (Kyotaro Horiguchi)

`initdb` used to work this way before v16, and now it does again. The change caused `initdb's --no-locale` option to not have the intended effect on `lc_messages`.

- In `pg_dump`, don't dump RLS policies or security labels for extension member objects (Tom Lane, Jacob Champion)

Previously, commands would be included in the dump to set these properties, which is really incorrect since they should be considered as internal affairs of the extension. Moreover, the restoring user might not have adequate privilege to set them, and indeed the dumping user might not have enough privilege to dump them (since dumping RLS policies requires acquiring lock on their table).

- In `pg_dump`, don't dump an extended statistics object if its underlying table isn't being dumped (Rian McGuire, Tom Lane)

This conforms to the behavior for other dependent objects such as indexes.

- Properly detect out-of-memory in one code path in `pg_dump` (Daniel Gustafsson)
- Make it an error for a `pgbench` script to end with an open pipeline (Anthonin Bonnefoy)

Previously, `pgbench` would behave oddly if a `\startpipeline` command lacked a matching `\endpipeline`. This seems like a scripting mistake rather than a case that `pgbench` needs to handle nicely, so throw an error.

- Fix crash in `contrib/intarray` if an array with an element equal to `INT_MAX` is inserted into a `gist__int_ops` index (Alexander Lakhin, Tom Lane)

- Report a better error when `contrib/pageinspect's hash_bitmap_info()` function is applied to a partitioned hash index (Alexander Lakhin, Michael Paquier)
- Report a better error when `contrib/pgstattuple's pgstathashindex()` function is applied to a partitioned hash index (Alexander Lakhin)
- On Windows, suppress autorun options when launching subprocesses in `pg_ctl` and `pg_regress` (Kyotaro Horiguchi)

When launching a child process via `cmd.exe`, pass the `/D` flag to prevent executing any autorun commands specified in the registry. This avoids possibly-surprising side effects.

- Move `is_valid_ascii()` from `mb/pg_wchar.h` to `utils/ascii.h` (Jubilee Young)

This change avoids the need to include `<simd.h>` in `pg_wchar.h`, which was causing problems for some third-party code.

- Fix compilation failures with libxml2 version 2.12.0 and later (Tom Lane)
- Fix compilation failure of `WAL_DEBUG` code on Windows (Bharath Rupireddy)
- Suppress compiler warnings from Python's header files (Peter Eisentraut, Tom Lane)

Our preferred compiler options provoke warnings about constructs appearing in recent versions of Python's header files. When using `gcc`, we can suppress these warnings with a `pragma`.

- Avoid deprecation warning when compiling with LLVM 18 (Thomas Munro)
- Update time zone data files to `tzdata` release 2024a for DST law changes in Greenland, Kazakhstan, and Palestine, plus corrections for the Antarctic stations Casey and Vostok. Also historical corrections for Vietnam, Toronto, and Miquelon. (Tom Lane)

E.21. Release 16.1

Release date: 2023-11-09

This release contains a variety of fixes from 16.0. For information about new features in major release 16, see [Section E.22](#).

E.21.1. Migration to Version 16.1

A dump/restore is not required for those running 16.X.

However, several mistakes have been discovered that could lead to certain types of indexes yielding wrong search results or being unnecessarily inefficient. It is advisable to `REINDEX` potentially-affected indexes after installing this update. See the fourth through seventh changelog entries below.

E.21.2. Changes

- Fix handling of unknown-type arguments in `DISTINCT "any"` aggregate functions (Tom Lane)

This error led to a `text`-type value being interpreted as an unknown-type value (that is, a zero-terminated string) at runtime. This could result in disclosure of server memory following the `text` value.

The PostgreSQL Project thanks Jingzhou Fu for reporting this problem. (CVE-2023-5868)

- Detect integer overflow while computing new array dimensions (Tom Lane)

When assigning new elements to array subscripts that are outside the current array bounds, an undetected integer overflow could occur in edge cases. Memory stomps that are potentially exploitable for arbitrary code execution are possible, and so is disclosure of server memory.

The PostgreSQL Project thanks Pedro Gallegos for reporting this problem. (CVE-2023-5869)

- Prevent the `pg_signal_backend` role from signalling background workers and autovacuum processes (Noah Misch, Jelte Fennema-Nio)

The documentation says that `pg_signal_backend` cannot issue signals to superuser-owned processes. It was able to signal these background processes, though, because they advertise a role OID of zero. Treat that as indicating superuser ownership. The security implications of cancelling one of these process types are fairly small so far as the core code goes (we'll just start another one), but extensions might add background workers that are more vulnerable.

Also ensure that the `is_superuser` parameter is set correctly in such processes. No specific security consequences are known for that oversight, but it might be significant for some extensions.

The PostgreSQL Project thanks Hemanth Sandrana and Mahendrakar Srinivasarao for reporting this problem. (CVE-2023-5870)

- Fix misbehavior during recursive page split in GiST index build (Heikki Linnakangas)

Fix a case where the location of a page downlink was incorrectly tracked, and introduce some logic to allow recovering from such situations rather than silently doing the wrong thing. This error could result in incorrect answers from subsequent index searches. It may be advisable to reindex all GiST indexes after installing this update.

- Prevent de-duplication of btree index entries for `interval` columns (Noah Misch)

There are `interval` values that are distinguishable but compare equal, for example `24:00:00` and `1 day`. This breaks assumptions made by btree de-duplication, so `interval` columns need to be excluded from de-duplication. This oversight can cause incorrect results from index-only scans. Moreover, after updating `amcheck` will report an error for almost all such indexes. Users should reindex any btree indexes on `interval` columns.

- Process `date` values more sanely in BRIN `datetime_minmax_multi_ops` indexes (Tomas Vondra)

The distance calculation for dates was backward, causing poor decisions about which entries to merge. The index still produces correct results, but is much less efficient than it should be. Reindexing BRIN `minmax_multi` indexes on `date` columns is advisable.

- Process large `timestamp` and `timestampz` values more sanely in BRIN `datetime_minmax_multi_ops` indexes (Tomas Vondra)

Infinites were mistakenly treated as having distance zero rather than a large distance from other values, causing poor decisions about which entries to merge. Also, finite-but-very-large values (near the endpoints of the representable timestamp range) could result in internal overflows, again causing poor decisions. The index still produces correct results, but is much less efficient than it should be. Reindexing BRIN `minmax_multi` indexes on `timestamp` and `timestampz` columns is advisable if the column contains, or has contained, infinities or large finite values.

- Avoid calculation overflows in BRIN `interval_minmax_multi_ops` indexes with extreme interval values (Tomas Vondra)

This bug might have caused unexpected failures while trying to insert large interval values into such an index.

- Fix partition step generation and runtime partition pruning for hash-partitioned tables with multiple partition keys (David Rowley)

Some cases involving an `IS NULL` condition on one of the partition keys could result in a crash.

- Fix inconsistent rechecking of concurrently-updated rows during `MERGE` (Dean Rasheed)

In `READ COMMITTED` mode, an update that finds that its target row was just updated by a concurrent transaction will recheck the query's `WHERE` conditions on the updated row. `MERGE` failed to ensure that the proper rows of other joined tables were used during this recheck, possibly resulting in incorrect decisions about whether the newly-updated row should be updated again by `MERGE`.

- Correctly identify the target table in an inherited `UPDATE/DELETE/MERGE` even when the parent table is excluded by constraints (Amit Langote, Tom Lane)

If the initially-named table is excluded by constraints, but not all its inheritance descendants are, the first non-excluded descendant was identified as the primary target table. This would lead to firing statement-level triggers associated with that table, rather than the initially-named table as should happen. In v16, the same oversight could also lead to “invalid perminfoindex 0 in RTE with relid NNNN” errors.

- Fix edge case in btree mark/restore processing of `ScalarArrayOpExpr` clauses (Peter Geoghegan)

When restoring an indexscan to a previously marked position, the code could miss required set-up steps if the scan had advanced exactly to the end of the matches for a `ScalarArrayOpExpr` (that is, an `indexcol = ANY (ARRAY[])`) clause. This could result in missing some rows that should have been fetched.

- Fix intra-query memory leak in Memoize execution (Orlov Aleksej, David Rowley)
- Fix intra-query memory leak when a set-returning function repeatedly returns zero rows (Tom Lane)
- Don't crash if `cursor_to_xmlschema()` is applied to a non-data-returning Portal (Boyu Yang)
- Fix improper sharing of origin filter condition across successive `pg_logical_slot_get_changes()` calls (Hou Zhijie)

The origin condition set by one call of this function would be re-used by later calls that did not specify the origin argument. This was not intended.

- Throw the intended error if `pgrowlocks()` is applied to a partitioned table (David Rowley)

Previously, a not-on-point complaint “only heap AM is supported” would be raised.

- Handle invalid indexes more cleanly in assorted SQL functions (Noah Misch)

Report an error if `pgstatindex()`, `pgstatginindex()`, `pgstathashindex()`, or `pgstattuple()` is applied to an invalid index. If `brin_desummarize_range()`, `brin_summarize_new_values()`, `brin_summarize_range()`, or `gin_clean_pending_list()` is applied to an invalid index, do nothing except to report a debug-level message. Formerly these functions attempted to process the index, and might fail in strange ways depending on what the failed `CREATE INDEX` had left behind.

- Avoid premature memory allocation failure with long inputs to `to_tsvector()` (Tom Lane)
- Fix over-allocation of the constructed `tsvector` in `tsvectorrecv()` (Denis Erokhin)

If the incoming vector includes position data, the binary receive function left wasted space (roughly equal to the size of the position data) in the finished `tsvector`. In extreme cases this could lead to “maximum total lexeme length exceeded” failures for vectors that were under the length limit when emitted. In any case it could lead to wasted space on-disk.

- Improve checks for corrupt PGLZ compressed data (Flavien Guedez)
- Fix `ALTER SUBSCRIPTION` so that a commanded change in the `run_as_owner` option is actually applied (Hou Zhijie)
- Fix bulk table insertion into partitioned tables (Andres Freund)

Improper sharing of insertion state across partitions could result in failures during `COPY FROM`, typically manifesting as “could not read block NNNN in file XXXX: read only 0 of 8192 bytes” errors.

- In `COPY FROM`, avoid evaluating column default values that will not be needed by the command (Laurenz Albe)

This avoids a possible error if the default value isn't actually valid for the column, or if the default's expression would fail in the current execution context. Such edge cases sometimes arise while

restoring dumps, for example. Previous releases did not fail in this situation, so prevent v16 from doing so.

- In `COPY FROM`, fail cleanly when an unsupported encoding conversion is needed (Tom Lane)

Recent refactoring accidentally removed the intended error check for this, such that it ended in “cache lookup failed for function 0” instead of a useful error message.

- Avoid crash in `EXPLAIN` if a parameter marked to be displayed by `EXPLAIN` has a NULL boot-time value (Xing Guo, Aleksander Alekseev, Tom Lane)

No built-in parameter fits this description, but an extension could define such a parameter.

- Ensure we have a snapshot while dropping `ON COMMIT DROP` temp tables (Tom Lane)

This prevents possible misbehavior if any catalog entries for the temp tables have fields wide enough to require toasting (such as a very complex `CHECK` condition).

- Avoid improper response to shutdown signals in child processes just forked by `system()` (Nathan Bossart)

This fix avoids a race condition in which a child process that has been forked off by `system()`, but hasn't yet exec'd the intended child program, might receive and act on a signal intended for the parent server process. That would lead to duplicate cleanup actions being performed, which will not end well.

- Cope with torn reads of `pg_control` in frontend programs (Thomas Munro)

On some file systems, reading `pg_control` may not be an atomic action when the server concurrently writes that file. This is detectable via a bad CRC. Retry a few times to see if the file becomes valid before we report error.

- Avoid torn reads of `pg_control` in relevant SQL functions (Thomas Munro)

Acquire the appropriate lock before reading `pg_control`, to ensure we get a consistent view of that file.

- Fix “could not find pathkey item to sort” errors occurring while planning aggregate functions with `ORDER BY` or `DISTINCT` options (David Rowley)
- Avoid integer overflow when computing size of backend activity string array (Jakub Wartak)

On 64-bit machines we will allow values of `track_activity_query_size` large enough to cause 32-bit overflow when multiplied by the allowed number of connections. The code actually allocating the per-backend local array was careless about this though, and allocated the array incorrectly.

- Fix briefly showing inconsistent progress statistics for `ANALYZE` on inherited tables (Heikki Linnakangas)

The block-level counters should be reset to zero at the same time we update the current-relation field.

- Fix the background writer to report any WAL writes it makes to the statistics counters (Nazir Bilal Yavuz)
- Fix confusion about forced-flush behavior in `pgstat_report_wal()` (Ryoga Yoshida, Michael Paquier)

This could result in some statistics about WAL I/O being forgotten in a shutdown.

- Fix statistics tracking of temporary-table extensions (Karina Litskevich, Andres Freund)

These were counted as normal-table writes when they should be counted as temp-table writes.

- When `track_io_timing` is enabled, include the time taken by relation extension operations as write time (Nazir Bilal Yavuz)

- Track the dependencies of cached `CALL` statements, and re-plan them when needed (Tom Lane)

DDL commands, such as replacement of a function that has been inlined into a `CALL` argument, can create the need to re-plan a `CALL` that has been cached by PL/pgSQL. That was not happening, leading to misbehavior or strange errors such as “cache lookup failed”.

- Avoid a possible `pfree-a-NULL-pointer` crash after an error in OpenSSL connection setup (Sergey Shinderuk)
- Track nesting depth correctly when inspecting `RECORD`-type Vars from outer query levels (Richard Guo)

This oversight could lead to assertion failures, core dumps, or “bogus varno” errors.

- Track hash function and negator function dependencies of `ScalarArrayOpExpr` plan nodes (David Rowley)

In most cases this oversight was harmless, since these functions would be unlikely to disappear while the node's original operator remains present.

- Fix error-handling bug in `RECORD` type cache management (Thomas Munro)

An out-of-memory error occurring at just the wrong point could leave behind inconsistent state that would lead to an infinite loop.

- Treat out-of-memory failures as fatal while reading WAL (Michael Paquier)

Previously this would be treated as a bogus-data condition, leading to the conclusion that we'd reached the end of WAL, which is incorrect and could lead to inconsistent WAL replay.

- Fix possible recovery failure due to trying to allocate memory based on a bogus WAL record length field (Thomas Munro, Michael Paquier)
- Fix “could not duplicate handle” error occurring on Windows when `min_dynamic_shared_memory` is set above zero (Thomas Munro)
- Fix order of operations in `GenericXLogFinish` (Jeff Davis)

This code violated the conditions required for crash safety by writing WAL before marking changed buffers dirty. No core code uses this function, but extensions do (`contrib/bloom` does, for example).

- Remove incorrect assertion in PL/Python exception handling (Alexander Lakhin)
- Fix `pg_dump` to dump the new `run_as_owner` option of subscriptions (Philip Warner)

Due to this oversight, subscriptions would always be restored with `run_as_owner` set to `false`, which is not equivalent to their behavior in pre-v16 releases.

- Fix `pg_restore` so that selective restores will include both table-level and column-level ACLs for selected tables (Euler Taveira, Tom Lane)

Formerly, only the table-level ACL would get restored if both types were present.

- Add logic to `pg_upgrade` to check for use of `abstime`, `reltime`, and `tinterval` data types (Álvaro Herrera)

These obsolete data types were removed in PostgreSQL version 12, so check to make sure they aren't present in an older database before claiming it can be upgraded.

- Avoid false “too many client connections” errors in `pgbench` on Windows (Noah Misch)
- Fix `vacuumdb`'s handling of multiple `-N` switches (Nathan Bossart, Kuwamura Masaki)

Multiple `-N` switches should exclude tables in multiple schemas, but in fact excluded nothing due to faulty construction of a generated query.

- Fix `vacuumdb` to honor its `--buffer-usage-limit` option in analyze-only mode (Ryoga Yoshida, David Rowley)
- In `contrib/amcheck`, do not report interrupted page deletion as corruption (Noah Misch)

This fix prevents false-positive reports of “the first child of leftmost target page is not leftmost of its level”, “block NNNN is not leftmost” or “left link/right link pair in index XXXX not in agreement”. They appeared if `amcheck` ran after an unfinished btree index page deletion and before `VACUUM` had cleaned things up.

- Fix failure of `contrib/btree_gin` indexes on interval columns, when an indexscan using the `<` or `<=` operator is performed (Dean Rasheed)

Such an indexscan failed to return all the entries it should.

- Add support for LLVM 16 and 17 (Thomas Munro, Dmitry Dolgov)
- Suppress assorted build-time warnings on recent macOS (Tom Lane)

Xcode 15 (released with macOS Sonoma) changed the linker's behavior in a way that causes many duplicate-library warnings while building PostgreSQL. These were harmless, but they're annoying so avoid citing the same libraries twice. Also remove use of the `-multiply_defined suppress linker` switch, which apparently has been a no-op for a long time, and is now actively complained of.

- When building `contrib/unaccent`'s rules file, fall back to using `python` if `--with-python` was not given and make variable `PYTHON` was not set (Japin Li)
- Remove `PHOT` (Phoenix Islands Time) from the default timezone abbreviations list (Tom Lane)

Presence of this abbreviation in the default list can cause failures on recent Debian and Ubuntu releases, as they no longer install the underlying `tzdb` entry by default. Since this is a made-up abbreviation for a zone with a total human population of about two dozen, it seems unlikely that anyone will miss it. If someone does, they can put it back via a custom abbreviations file.

E.22. Release 16

Release date: 2023-09-14

E.22.1. Overview

PostgreSQL 16 contains many new features and enhancements, including:

- Allow parallelization of `FULL` and internal right `OUTER` hash joins
- Allow logical replication from standby servers
- Allow logical replication subscribers to apply large transactions in parallel
- Allow monitoring of I/O statistics using the new `pg_stat_io` view
- Add SQL/JSON constructors and identity functions
- Improve performance of vacuum freezing
- Add support for regular expression matching of user and database names in `pg_hba.conf`, and user names in `pg_ident.conf`

The above items and other new features of PostgreSQL 16 are explained in more detail in the sections below.

E.22.2. Migration to Version 16

A dump/restore using [pg_dumpall](#) or use of [pg_upgrade](#) or logical replication is required for those wishing to migrate data from any previous release. See [Section 17.6](#) for general information on migrating to new major releases.

Version 16 contains a number of changes that may affect compatibility with previous releases. Observe the following incompatibilities:

- Change assignment rules for [PL/pgSQL](#) bound cursor variables (Tom Lane)

Previously, the string value of such variables was set to match the variable name during cursor assignment; now it will be assigned during [OPEN](#), and will not match the variable name. To restore the previous behavior, assign the desired portal name to the cursor variable before [OPEN](#).

- Disallow [NULLS NOT DISTINCT](#) indexes for primary keys (Daniel Gustafsson)
- Change [REINDEX DATABASE](#) and [reindexdb](#) to not process indexes on system catalogs (Simon Riggs)

Processing such indexes is still possible using [REINDEX SYSTEM](#) and [reindexdb --system](#).

- Tighten [GENERATED](#) expression restrictions on inherited and partitioned tables (Amit Langote, Tom Lane)

Columns of parent/partitioned and child/partition tables must all have the same generation status, though now the actual generation expressions can be different.

- Remove [pg_walinspect](#) functions [pg_get_wal_records_info_till_end_of_wal\(\)](#) and [pg_get_wal_stats_till_end_of_wal\(\)](#) (Bharath Rupireddy)
- Rename server variable [force_parallel_mode](#) to [debug_parallel_query](#) (David Rowley)
- Remove the ability to [create views](#) manually with [ON SELECT](#) rules (Tom Lane)
- Remove the server variable [vacuum_defer_cleanup_age](#) (Andres Freund)

This has been unnecessary since [hot_standby_feedback](#) and [replication slots](#) were added.

- Remove server variable [promote_trigger_file](#) (Simon Riggs)

This was used to promote a standby to primary, but is now more easily accomplished with [pg_ctl promote](#) or [pg_promote\(\)](#).

- Role inheritance now controls the default inheritance status of member roles added during [GRANT](#) (Robert Haas)

The role's default inheritance behavior can be overridden with the new [GRANT ... WITH INHERIT](#) clause. This allows inheritance of some roles and not others because the members' inheritance status is set at [GRANT](#) time. Previously the inheritance status of member roles was controlled only by the role's inheritance status, and changes to a role's inheritance status affected all previous and future member roles.

- Restrict the privileges of [CREATEROLE](#) and its ability to modify other roles (Robert Haas)

Previously roles with [CREATEROLE](#) privileges could change many aspects of any non-superuser role. Such changes, including adding members, now require the role requesting the change to have [ADMIN OPTION](#) permission. For example, they can now change the [CREATEDB](#), [REPLICATION](#), and [BYPASSRLS](#) properties only if they also have those permissions.

- Remove symbolic links for the postmaster binary (Peter Eisentraut)

E.22.3. Changes

Below you will find a detailed account of the changes between PostgreSQL 16 and the previous major release.

E.22.3.1. Server

E.22.3.1.1. Optimizer

- Allow incremental sorts in more cases, including [DISTINCT](#) (David Rowley)

- Add the ability for aggregates having `ORDER BY` or `DISTINCT` to use pre-sorted data (David Rowley)

The new server variable `enable_presorted_aggregate` can be used to disable this.

- Allow memoize atop a `UNION ALL` (Richard Guo)
- Allow anti-joins to be performed with the non-nullable input as the inner relation (Richard Guo)
- Allow parallelization of `FULL` and internal right `OUTER` hash joins (Melanie Plageman, Thomas Munro)
- Improve the accuracy of `GIN` index access optimizer costs (Ronan Dunklau)

E.22.3.1.2. General Performance

- Allow more efficient addition of heap and index pages (Andres Freund)
- During non-freeze operations, perform page `freezing` where appropriate (Peter Geoghegan)
- This makes full-table freeze vacuums less necessary.
- Allow window functions to use the faster `ROWS` mode internally when `RANGE` mode is active but unnecessary (David Rowley)
- Allow optimization of always-increasing window functions `ntile()`, `cume_dist()` and `percent_rank()` (David Rowley)
- Allow aggregate functions `string_agg()` and `array_agg()` to be parallelized (David Rowley)
- Improve performance by caching `RANGE` and `LIST` partition lookups (Amit Langote, Hou Zhijie, David Rowley)
- Allow control of the shared buffer usage by vacuum and analyze (Melanie Plageman)

The `VACUUM/ANALYZE` option is `BUFFER_USAGE_LIMIT`, and the `vacuumdb` option is `--buffer-usage-limit`. The default value is set by server variable `vacuum_buffer_usage_limit`, which also controls autovacuum.

- Support `wal_sync_method=fdatasync` on Windows (Thomas Munro)
- Allow `HOT` updates if only `BRIN`-indexed columns are updated (Matthias van de Meent, Josef Simanek, Tomas Vondra)
- Improve the speed of updating the `process title` (David Rowley)
- Allow `xid/subxid` searches and ASCII string detection to use vector operations (Nathan Bossart, John Naylor)

ASCII detection is particularly useful for `COPY FROM`. Vector operations are also used for some C array searches.

- Reduce overhead of memory allocations (Andres Freund, David Rowley)

E.22.3.1.3. Monitoring

- Add system view `pg_stat_io` view to track I/O statistics (Melanie Plageman)
- Record statistics on the last sequential and index scans on tables (Dave Page)

This information appears in `pg_stat_*_tables` and `pg_stat_*_indexes`.

- Record statistics on the occurrence of updated rows moving to new pages (Corey Huinker)

The `pg_stat_*_tables` column is `n_tup_newpage_upd`.

- Add speculative lock information to the `pg_locks` system view (Masahiko Sawada, Noriyoshi Shindo)

The transaction id is displayed in the `transactionid` column and the speculative insertion token is displayed in the `objid` column.

- Add the display of prepared statement result types to the `pg_prepared_statements` view (Dagfinn Ilmari Mannsåker)
- Create subscription statistics entries at subscription creation time so `stats_reset` is accurate (Andres Freund)

Previously entries were created only when the first statistics were reported.

- Correct the I/O accounting for temp relation writes shown in `pg_stat_database` (Melanie Plageman)
- Add function `pg_stat_get_backend_subxact()` to report on a session's subtransaction cache (Dilip Kumar)
- Have `pg_stat_get_backend_idset()`, `pg_stat_get_backend_activity()`, and related functions use the unchanging backend id (Nathan Bossart)

Previously the index values might change during the lifetime of the session.

- Report stand-alone backends with a special backend type (Melanie Plageman)
- Add wait event `SpinDelay` to report spinlock sleep delays (Andres Freund)
- Create new wait event `DSMAllocate` to indicate waiting for dynamic shared memory allocation (Thomas Munro)

Previously this type of wait was reported as `DSMFillZeroWrite`, which was also used by `mmap()` allocations.

- Add the database name to the `process title` of logical WAL senders (Tatsuhiko Nakamori)

Physical WAL senders do not display a database name.

- Add checkpoint and REDO LSN information to `log_checkpoints` messages (Bharath Rupireddy, Kyotaro Horiguchi)
- Provide additional details during client certificate failures (Jacob Champion)

E.22.3.1.4. Privileges

- Add predefined role `pg_create_subscription` with permission to create subscriptions (Robert Haas)
- Allow subscriptions to not require passwords (Robert Haas)

This is accomplished with the option `password_required=false`.

- Simplify permissions for `LOCK TABLE` (Jeff Davis)

Previously a user's ability to perform `LOCK TABLE` at various lock levels was limited to the lock levels required by the commands they had permission to execute on the table. For example, someone with `UPDATE` permission could perform all lock levels except `ACCESS SHARE`, even though it was a lesser lock level. Now users can issue lesser lock levels if they already have permission for greater lock levels.

- Allow `ALTER GROUP group_name ADD USER user_name` to be performed with `ADMIN OPTION` (Robert Haas)

Previously `CREATEROLE` permission was required.

- Allow `GRANT` to use `WITH ADMIN TRUE/FALSE` syntax (Robert Haas)

Previously only the `WITH ADMIN OPTION` syntax was supported.

- Allow roles that create other roles to automatically inherit the new role's rights or the ability to `SET ROLE` to the new role (Robert Haas, Shi Yu)

This is controlled by server variable `createrole_self_grant`.

- Prevent users from changing the default privileges of non-inherited roles (Robert Haas)

This is now only allowed for inherited roles.

- When granting role membership, require the granted-by role to be a role that has appropriate permissions (Robert Haas)

This is a requirement even when a non-bootstrap superuser is granting role membership.

- Allow non-superusers to grant permissions using a granted-by user that is not the current user (Robert Haas)

The current user still must have sufficient permissions given by the specified granted-by user.

- Add `GRANT` to control permission to use `SET ROLE` (Robert Haas)

This is controlled by a new `GRANT ... SET` option.

- Add dependency tracking to roles which have granted privileges (Robert Haas)

For example, removing `ADMIN OPTION` will fail if there are privileges using that option; `CASCADE` must be used to revoke dependent permissions.

- Add dependency tracking of grantors for `GRANT` records (Robert Haas)

This guarantees that `pg_auth_members.grantor` values are always valid.

- Allow multiple role membership records (Robert Haas)

Previously a new membership grant would remove a previous matching membership grant, even if other aspects of the grant did not match.

- Prevent removal of superuser privileges for the bootstrap user (Robert Haas)

Restoring such users could lead to errors.

- Allow `makeaclitem()` to accept multiple privilege names (Robins Tharakan)

Previously only a single privilege name, like `SELECT`, was accepted.

E.22.3.1.5. Server Configuration

- Add support for Kerberos credential delegation (Stephen Frost)

This is enabled with server variable `gss_accept_delegation` and libpq connection parameter `gss-delegation`.

- Allow the SCRAM iteration count to be set with server variable `scram_iterations` (Daniel Gustafsson)
- Improve performance of server variable management (Tom Lane)
- Tighten restrictions on which server variables can be reset (Masahiko Sawada)

Previously, while certain variables, like `transaction_isolation`, were not affected by `RESET ALL`, they could be individually reset in inappropriate situations.

- Move various `postgresql.conf` items into new categories (Shinya Kato)

This also affects the categories displayed in the `pg_settings` view.

- Prevent configuration file recursion beyond 10 levels (Julien Rouhaud)
- Allow `autovacuum` to more frequently honor changes to delay settings (Melanie Plageman)

Rather than honor changes only at the start of each relation, honor them at the start of each block.

- Remove restrictions that archive files be durably renamed (Nathan Bossart)

The `archive_command` command is now more likely to be called with already-archived files after a crash.

- Prevent `archive_library` and `archive_command` from being set at the same time (Nathan Bossart)

Previously `archive_library` would override `archive_command`.

- Allow the postmaster to terminate children with an abort signal (Tom Lane)

This allows collection of a core dump for a stuck child process. This is controlled by `send_abort_for_crash` and `send_abort_for_kill`. The postmaster's `-T` switch is now the same as setting `send_abort_for_crash`.

- Remove the non-functional postmaster `-n` option (Tom Lane)
- Allow the server to reserve backend slots for roles with `pg_use_reserved_connections` membership (Nathan Bossart)

The number of reserved slots is set by server variable `reserved_connections`.

- Allow `huge pages` to work on newer versions of Windows 10 (Thomas Munro)

This adds the special handling required to enable huge pages on newer versions of Windows 10.

- Add `debug_io_direct` setting for developer usage (Thomas Munro, Andres Freund, Bharath Rupireddy)

While primarily for developers, `wal_sync_method=open_sync/open_datasync` has been modified to not use direct I/O with `wal_level=minimal`; this is now enabled with `debug_io_direct=wal`.

- Add function `pg_split_walfile_name()` to report the segment and timeline values of WAL file names (Bharath Rupireddy)

E.22.3.1.6. `pg_hba.conf`

- Add support for regular expression matching on database and role entries in `pg_hba.conf` (Bertrand Drouvot)

Regular expression patterns are prefixed with a slash. Database and role names that begin with slashes need to be double-quoted if referenced in `pg_hba.conf`.

- Improve user-column handling of `pg_ident.conf` to match `pg_hba.conf` (Jelte Fennema)

Specifically, add support for `all`, role membership with `+`, and regular expressions with a leading slash. Any user name that matches these patterns must be double-quoted.

- Allow include files in `pg_hba.conf` and `pg_ident.conf` (Julien Rouhaud)

These are controlled by `include`, `include_if_exists`, and `include_dir`. System views `pg_hba_file_rules` and `pg_ident_file_mappings` now display the file name.

- Allow `pg_hba.conf` tokens to be of unlimited length (Tom Lane)
- Add rule and map numbers to the system view `pg_hba_file_rules` (Julien Rouhaud)

E.22.3.1.7. Localization

- Determine the default encoding from the locale when using ICU (Jeff Davis)

Previously the default was always UTF-8.

- Have `CREATE DATABASE` and `CREATE COLLATION`'s `LOCALE` options, and `initdb` and `createdb --locale` options, control non-libc collation providers (Jeff Davis)

Previously they only controlled libc providers.

- Add predefined collations `unicode` and `ucs_basic` (Peter Eisentraut)

This only works if ICU support is enabled.

- Allow custom ICU collation rules to be created (Peter Eisentraut)

This is done using `CREATE COLLATION`'s new `RULES` clause, as well as new options for `CREATE DATABASE`, `createdb`, and `initdb`.

- Allow Windows to import system locales automatically (Juan José Santamaría Flecha)

Previously, only ICU locales could be imported on Windows.

E.22.3.2. Logical Replication

- Allow `logical decoding` on standbys (Bertrand Drouvot, Andres Freund, Amit Khandekar)

Snapshot WAL records are required for logical slot creation but cannot be created on standbys. To avoid delays, the new function `pg_log_standby_snapshot()` allows creation of such records.

- Add server variable to control how logical decoding publishers transfer changes and how subscribers apply them (Shi Yu)

The variable is `debug_logical_replication_streaming`.

- Allow logical replication initial table synchronization to copy rows in binary format (Melih Mutlu)

This is only possible for subscriptions marked as binary.

- Allow parallel application of logical replication (Hou Zhijie, Wang Wei, Amit Kapila)

The `CREATE SUBSCRIPTION` `STREAMING` option now supports `parallel` to enable application of large transactions by parallel workers. The number of parallel workers is controlled by the new server variable `max_parallel_apply_workers_per_subscription`. Wait events `LogicalParallelApplyMain`, `LogicalParallelApplyStateChange`, and `LogicalApplySendData` were also added. Column `leader_pid` was added to system view `pg_stat_subscription` to track parallel activity.

- Improve performance for `logical replication apply` without a primary key (Onder Kalaci, Amit Kapila)

Specifically, `REPLICA IDENTITY FULL` can now use btree indexes rather than sequentially scanning the table to find matches.

- Allow logical replication subscribers to process only changes that have no origin (Vignesh C, Amit Kapila)

This can be used to avoid replication loops. This is controlled by the new `CREATE SUBSCRIPTION ... ORIGIN` option.

- Perform logical replication `SELECT` and DML actions as the table owner (Robert Haas)

This improves security and now requires subscription owners to be either superusers or to have `SET ROLE` permission on all roles owning tables in the replication set. The previous behavior of performing all operations as the subscription owner can be enabled with the subscription `run_as_owner` option.

- Have `wal_retrieve_retry_interval` operate on a per-subscription basis (Nathan Bossart)

Previously the retry time was applied globally. This also adds wait events `>LogicalRepLauncherDSA` and `LogicalRepLauncherHash`.

E.22.3.3. Utility Commands

- Add `EXPLAIN` option `GENERIC_PLAN` to display the generic plan for a parameterized query (Laurenz Albe)
- Allow a `COPY FROM` value to map to a column's `DEFAULT` (Israel Barth Rubio)
- Allow `COPY` into foreign tables to add rows in batches (Andrey Lepikhov, Etsuro Fujita)

This is controlled by the `postgres_fdw` option `batch_size`.

- Allow the `STORAGE` type to be specified by `CREATE TABLE` (Teodor Sigaev, Aleksander Alekseev)

Previously only `ALTER TABLE` could control this.

- Allow `truncate triggers` on foreign tables (Yugo Nagata)
- Allow `VACUUM` and `vacuumdb` to only process `TOAST` tables (Nathan Bossart)

This is accomplished by having `VACUUM` turn off `PROCESS_MAIN` or by `vacuumdb` using the `--no-process-main` option.

- Add `VACUUM` options to skip or update all `frozen` statistics (Tom Lane, Nathan Bossart)

The options are `SKIP_DATABASE_STATS` and `ONLY_DATABASE_STATS`.

- Change `REINDEX DATABASE` and `REINDEX SYSTEM` to no longer require an argument (Simon Riggs)

Previously the database name had to be specified.

- Allow `CREATE STATISTICS` to generate a statistics name if none is specified (Simon Riggs)

E.22.3.4. Data Types

- Allow non-decimal `integer literals` (Peter Eisentraut)

For example, `0x42F`, `0o273`, and `0b100101`.

- Allow `NUMERIC` to process hexadecimal, octal, and binary integers of any size (Dean Rasheed)

Previously only unquoted eight-byte integers were supported with these non-decimal bases.

- Allow underscores in integer and numeric `constants` (Peter Eisentraut, Dean Rasheed)

This can improve readability for long strings of digits.

- Accept the spelling `+infinity` in datetime input (Vik Fearing)
- Prevent the specification of `epoch` and `infinity` together with other fields in datetime strings (Joseph Koshakow)
- Remove undocumented support for date input in the form `YyearMmonthDday` (Joseph Koshakow)
- Add functions `pg_input_is_valid()` and `pg_input_error_info()` to check for type conversion errors (Tom Lane)

E.22.3.5. General Queries

- Allow subqueries in the `FROM` clause to omit aliases (Dean Rasheed)
- Add support for enhanced numeric literals in SQL/JSON paths (Peter Eisentraut)

For example, allow hexadecimal, octal, and binary integers and underscores between digits.

E.22.3.6. Functions

- Add SQL/JSON constructors (Nikita Glukhov, Teodor Sigaev, Oleg Bartunov, Alexander Korotkov, Amit Langote)

The new functions `JSON_ARRAY()`, `JSON_ARRAYAGG()`, `JSON_OBJECT()`, and `JSON_OBJECTAGG()` are part of the SQL standard.

- Add SQL/JSON object checks (Nikita Glukhov, Teodor Sigaev, Oleg Bartunov, Alexander Korotkov, Amit Langote, Andrew Dunstan)

The `IS JSON` checks include checks for values, arrays, objects, scalars, and unique keys.

- Allow JSON string parsing to use vector operations (John Naylor)
- Improve the handling of full text highlighting function `ts_headline()` for `OR` and `NOT` expressions (Tom Lane)
- Add functions to add, subtract, and generate `timestampz` values in a specified time zone (Przemyslaw Sztach, Gurjeet Singh)

The functions are `date_add()`, `date_subtract()`, and `generate_series()`.

- Change `date_trunc(unit, timestampz, time_zone)` to be an immutable function (Przemyslaw Sztach)

This allows the creation of expression indexes using this function.

- Add server variable `SYSTEM_USER` (Bertrand Drouvot)

This reports the authentication method and its authenticated user.

- Add functions `array_sample()` and `array_shuffle()` (Martin Kalcher)
- Add aggregate function `ANY_VALUE()` which returns any value from a set (Vik Fearing)
- Add function `random_normal()` to supply normally-distributed random numbers (Paul Ramsey)
- Add error function `erf()` and its complement `erfc()` (Dean Rasheed)
- Improve the accuracy of numeric `power()` for integer exponents (Dean Rasheed)
- Add `XMLSERIALIZE()` option `INDENT` to pretty-print its output (Jim Jones)
- Change `pg_collation_actual_version()` to return a reasonable value for the default collation (Jeff Davis)

Previously it returned `NULL`.

- Allow `pg_read_file()` and `pg_read_binary_file()` to ignore missing files (Kyotaro Horiguchi)
- Add byte specification (B) to `pg_size_bytes()` (Peter Eisentraut)
- Allow `to_reg*` functions to accept numeric OIDs as input (Tom Lane)

E.22.3.7. PL/pgSQL

- Add the ability to get the current function's OID in PL/pgSQL (Pavel Stehule)

This is accomplished with `GET DIAGNOSTICS variable = PG_ROUTINE_OID`.

E.22.3.8. libpq

- Add libpq connection option `require_auth` to specify a list of acceptable authentication methods (Jacob Champion)

This can also be used to disallow certain authentication methods.

- Allow multiple libpq-specified hosts to be randomly selected (Jelte Fennema)

This is enabled with `load_balance_hosts=random` and can be used for load balancing.

- Add libpq option `sslcertmode` to control transmission of the client certificate (Jacob Champion)

The option values are `disable`, `allow`, and `require`.

- Allow libpq to use the system certificate pool for certificate verification (Jacob Champion, Thomas Habets)

This is enabled with `sslrootcert=system`, which also enables `sslmode=verify-full`.

E.22.3.9. Client Applications

- Allow `ECPG` variable declarations to use typedef names that match unreserved SQL keywords (Tom Lane)

This change does prevent keywords which match C typedef names from being processed as keywords in later `EXEC SQL` blocks.

- Allow `psql` to control the maximum width of header lines in expanded format (Platon Pronko)

This is controlled by `xheader_width`.

- Add `psql` command `\drg` to show role membership details (Pavel Luzanov)

The `Member` of output column has been removed from `\du` and `\dg` because this new command displays this information in more detail.

- Allow `psql`'s access privilege commands to show system objects (Nathan Bossart)

The options are `\dpS` and `\zS`.

- Add `FOREIGN` designation to `psql \d+` for foreign table children and partitions (Ian Lawrence Barwick)

- Prevent `\df+` from showing function source code (Isaac Morland)

Function bodies are more easily viewed with `\sf`.

- Allow `psql` to submit queries using the extended query protocol (Peter Eisentraut)

Passing arguments to such queries is done using the new `psql \bind` command.

- Allow `psql \watch` to limit the number of executions (Andrey Borodin)

The `\watch` options can now be named when specified.

- Detect invalid values for `psql \watch`, and allow zero to specify no delay (Andrey Borodin)

- Allow `psql` scripts to obtain the exit status of shell commands and queries (Corey Huinker, Tom Lane)

The new `psql` control variables are `SHELL_ERROR` and `SHELL_EXIT_CODE`.

- Various `psql` tab completion improvements (Vignesh C, Aleksander Alekseev, Dagfinn Ilmari Mannsåker, Shi Yu, Michael Paquier, Ken Kato, Peter Smith)

E.22.3.9.2. `pg_dump`

- Add `pg_dump` control of dumping child tables and partitions (Gilles Darold)

The new options are `--table-and-children`, `--exclude-table-and-children`, and `--exclude-table-data-and-children`.

- Add LZ4 and Zstandard compression to `pg_dump` (Georgios Kokolatos, Justin Pryzby)
- Allow `pg_dump` and `pg_basebackup` to use `long` mode for compression (Justin Pryzby)
- Improve `pg_dump` to accept a more consistent compression syntax (Georgios Kokolatos)

Options like `--compress=gzip:5`.

E.22.3.10. Server Applications

- Add `initdb` option to set server variables for the duration of `initdb` and all future server starts (Tom Lane)

The option is `-c name=value`.

- Add options to `createuser` to control more user options (Shinya Kato)

Specifically, the new options control the valid-until date, bypassing of row-level security, and role membership.

- Deprecate `createuser` option `--role` (Nathan Bossart)

This option could be easily confused with new `createuser` role membership options, so option `--member-of` has been added with the same functionality. The `--role` option can still be used.

- Allow control of `vacuumdb` schema processing (Gilles Darold)

These are controlled by options `--schema` and `--exclude-schema`.

- Use new `VACUUM` options to improve the performance of `vacuumdb` (Tom Lane, Nathan Bossart)
- Have `pg_upgrade` set the new cluster's locale and encoding (Jeff Davis)

This removes the requirement that the new cluster be created with the same locale and encoding settings.

- Add `pg_upgrade` option to specify the default transfer mode (Peter Eisentraut)

The option is `--copy`.

- Improve `pg_basebackup` to accept numeric compression options (Georgios Kokolatos, Michael Paquier)

Options like `--compress=server-5` are now supported.

- Fix `pg_basebackup` to handle tablespaces stored in the `PGDATA` directory (Robert Haas)
- Add `pg_waldump` option `--save-fullpage` to dump full page images (David Christensen)
- Allow `pg_waldump` options `-t/--timeline` to accept hexadecimal values (Peter Eisentraut)
- Add support for progress reporting to `pg_verifybackup` (Masahiko Sawada)
- Allow `pg_rewind` to properly track timeline changes (Heikki Linnakangas)

Previously if `pg_rewind` was run after a timeline switch but before a checkpoint was issued, it might incorrectly determine that a rewind was unnecessary.

- Have `pg_receivewal` and `pg_recvlogical` cleanly exit on `SIGTERM` (Christoph Berg)

This signal is often used by `systemd`.

E.22.3.11. Source Code

- Build ICU support by default (Jeff Davis)

This removes build flag `--with-icu` and adds flag `--without-icu`.

- Add support for SSE2 (Streaming SIMD Extensions 2) vector operations on x86-64 architectures (John Naylor)
- Add support for Advanced SIMD (Single Instruction Multiple Data) (NEON) instructions on ARM architectures (Nathan Bossart)
- Have Windows binaries built with MSVC use `RandomizedBaseAddress` (ASLR) (Michael Paquier)

This was already enabled on MinGW builds.

- Prevent extension libraries from exporting their symbols by default (Andres Freund, Tom Lane)

Functions that need to be called from the core backend or other extensions must now be explicitly marked `PGDLL_EXPORT`.

- Require Windows 10 or newer versions (Michael Paquier, Juan José Santamaría Flecha)

Previously Windows Vista and Windows XP were supported.

- Require Perl version 5.14 or later (John Naylor)
- Require Bison version 2.3 or later (John Naylor)
- Require Flex version 2.5.35 or later (John Naylor)
- Require MIT Kerberos for GSSAPI support (Stephen Frost)
- Remove support for Visual Studio 2013 (Michael Paquier)
- Remove support for HP-UX (Thomas Munro)
- Remove support for HP/Intel Itanium (Thomas Munro)
- Remove support for M68K, M88K, M32R, and SuperH CPU architectures (Thomas Munro)
- Remove `libpq` support for SCM credential authentication (Michael Paquier)

Backend support for this authentication method was removed in PostgreSQL 9.1.

- Add meson build system (Andres Freund, Nazir Bilal Yavuz, Peter Eisentraut)

This eventually will replace the Autoconf and Windows-based MSVC build systems.

- Allow control of the location of the openssl binary used by the build system (Peter Eisentraut)

Make finding openssl program a configure or meson option

- Add build option to allow testing of small table segment sizes (Andres Freund)

The build options are `--with-segsize-blocks` and `-Dsegsize_blocks`.

- Add `pgindent` options (Andrew Dunstan)

The new options are `--show-diff`, `--silent-diff`, `--commit`, and `--help`, and allow multiple `--exclude` options. Also require the typedef file to be explicitly specified. Options `--code-base` and `--build` were also removed.

- Add `pg_bsd_indent` source code to the main tree (Tom Lane)
- Improve `make_ctags` and `make_etags` (Yugo Nagata)
- Adjust `pg_attribute` columns for efficiency (Peter Eisentraut)

E.22.3.12. Additional Modules

- Improve use of extension-based indexes on boolean columns (Zongliang Quan, Tom Lane)
- Add support for Daitch-Mokotoff Soundex to `fuzzystrmatch` (Dag Lem)
- Allow `auto_explain` to log values passed to parameterized statements (Dagfinn Ilmari Mannsåker)

This affects queries using server-side `PREPARE/EXECUTE` and client-side parse/bind. Logging is controlled by `auto_explain.log_parameter_max_length`; by default query parameters will be logged with no length restriction.

- Have `auto_explain`'s `log_verbose` mode honor the value of `compute_query_id` (Atsushi Torikoshi)

Previously even if `compute_query_id` was enabled, `log_verbose` was not showing the query identifier.

- Change the maximum length of `ltree` labels from 256 to 1000 and allow hyphens (Garen Torikian)
- Have `pg_stat_statements` normalize constants used in utility commands (Michael Paquier)

Previously constants appeared instead of placeholders, e.g., `$1`.

- Add `pg_walinspect` function `pg_get_wal_block_info()` to report WAL block information (Michael Paquier, Melanie Plageman, Bharath Rupireddy)
- Change how `pg_walinspect` functions `pg_get_wal_records_info()` and `pg_get_wal_stats()` interpret ending LSNs (Bharath Rupireddy)

Previously ending LSNs which represent nonexistent WAL locations would generate an error, while they will now be interpreted as the end of the WAL.

- Add detailed descriptions of WAL records in `pg_walinspect` and `pg_waldump` (Melanie Plageman, Peter Geoghegan)
- Add `pageinspect` function `bt_multi_page_stats()` to report statistics on multiple pages (Hamid Akhtar)

This is similar to `bt_page_stats()` except it can report on a range of pages.

- Add empty range output column to `pageinspect` function `brin_page_items()` (Tomas Vondra)
- Redesign archive modules to be more flexible (Nathan Bossart)

Initialization changes will require modules written for older versions of Postgres to be updated.

- Correct inaccurate `pg_stat_statements` row tracking extended query protocol statements (Sami Imseih)
- Add `pg_buffercache` function `pg_buffercache_usage_counts()` to report usage totals (Nathan Bossart)
- Add `pg_buffercache` function `pg_buffercache_summary()` to report summarized buffer statistics (Melih Mutlu)
- Allow the schemas of required extensions to be referenced in extension scripts using the new syntax `@extschema:referenced_extension_name@` (Regina Obe)
- Allow required extensions to be marked as non-relocatable using `no_relocate` (Regina Obe)

This allows `@extschema:referenced_extension_name@` to be treated as a constant for the lifetime of the extension.

E.22.3.12.1. postgres_fdw

- Allow `postgres_fdw` to do aborts in parallel (Etsuro Fujita)

This is enabled with `postgres_fdw` option `parallel_abort`.

- Make `ANALYZE` on foreign `postgres_fdw` tables more efficient (Tomas Vondra)

The `postgres_fdw` option `analyze_sampling` controls the sampling method.

- Restrict shipment of `reg*` type constants in `postgres_fdw` to those referencing built-in objects or extensions marked as shippable (Tom Lane)
- Have `postgres_fdw` and `dblink` handle interrupts during connection establishment (Andres Freund)

E.22.4. Acknowledgments

E.23. Prior Releases

Release notes for prior versions can be found online. At the time of Postgres Pro Standard 16 release, these prior versions were supported:

- Postgres Pro Standard 15: <https://postgrespro.com/docs/postgrespro/15/release.html>
- Postgres Pro Standard 14: <https://postgrespro.com/docs/postgrespro/14/release.html>
- Postgres Pro Standard 13: <https://postgrespro.com/docs/postgrespro/13/release.html>
- Postgres Pro Standard 12: <https://postgrespro.com/docs/postgrespro/12/release.html>
- Postgres Pro Standard 11: <https://postgrespro.com/docs/postgrespro/11/release.html>

Appendix F. Additional Supplied Modules and Extensions Shipped in postgrespro-std-16-contrib

This appendix, [Appendix G](#), and [Appendix I](#) contain information on the optional components available in the Postgres Pro Standard distribution. These include porting tools, analysis utilities, and plug-in features that are not part of the core Postgres Pro system. They are separate mainly because they address a limited audience or are too experimental to be part of the main source tree. This does not preclude their usefulness.

This appendix and [Appendix G](#) cover the extensions and other server plug-in modules. [Appendix I](#) covers the utility programs.

Many components supply new user-defined functions, operators, or types, packaged as *extensions*. To make use of one of these extensions, after you have installed the code you need to register the new SQL objects in the database system. This is done by executing a [CREATE EXTENSION](#) command. In a fresh database, you can simply do

```
CREATE EXTENSION extension_name;
```

This command registers the new SQL objects in the current database only, so you need to run it in every database in which you want the extension's facilities to be available. Alternatively, run it in database `template1` so that the extension will be copied into subsequently-created databases by default.

For all extensions, the `CREATE EXTENSION` command must be run by a database superuser, unless the extension is considered “trusted”. Trusted extensions can be run by any user who has `CREATE` privilege on the current database. Extensions that are trusted are identified as such in the sections that follow. Generally, trusted extensions are ones that cannot provide access to outside-the-database functionality.

The following extensions are trusted in a default installation:

btree_gin	fuzzystrmatch	ltree	tcn
btree_gist	hstore	pgcrypto	tsm_system_rows
citext	intarray	pg_trgm	tsm_system_time
cube	isn	seg	unaccent
dict_int	lo	tablefunc	uuid-oss

Many extensions allow you to install their objects in a schema of your choice. To do that, add `SCHEMA schema_name` to the `CREATE EXTENSION` command. By default, the objects will be placed in your current creation target schema, which in turn defaults to `public`.

Note, however, that some of these components are not “extensions” in this sense, but are loaded into the server in some other way, for instance by way of [shared_preload_libraries](#). See the documentation of each component for details.

This appendix contains modules and extensions that are made available in Postgres Pro Standard as a separate subpackage `postgrespro-std-16-contrib`. Note that the `toastapi` extension to add custom TOASTers is also available in `postgrespro-std-16-contrib` (see [Section 70.2.3](#) for details).

F.1. adminpack — pgAdmin support toolpack

`adminpack` provides a number of support functions which pgAdmin and other administration and management tools can use to provide additional functionality, such as remote management of server log files. Use of all these functions is only allowed to database superusers by default, but may be allowed to other users by using the `GRANT` command.

The functions shown in [Table F.1](#) provide write access to files on the machine hosting the server. (See also the functions in [Table 9.102](#), which provide read-only access.) Only files within the database cluster directory can be accessed, unless the user is a superuser or given privileges of one of the `pg_read_server_files` or `pg_write_server_files` roles, as appropriate for the function, but either a relative or absolute path is allowable.

Table F.1. adminpack Functions

Function	Description
<code>pg_catalog.pg_file_write</code> (<i>filename</i> text, <i>data</i> text, <i>append</i> boolean) → bigint	Writes, or appends to, a text file.
<code>pg_catalog.pg_file_sync</code> (<i>filename</i> text) → void	Flushes a file or directory to disk.
<code>pg_catalog.pg_file_rename</code> (<i>oldname</i> text, <i>newname</i> text [, <i>archivename</i> text]) → boolean	Renames a file.
<code>pg_catalog.pg_file_unlink</code> (<i>filename</i> text) → boolean	Removes a file.
<code>pg_catalog.pg_logdir_ls</code> () → setof record	Lists the log files in the <code>log_directory</code> directory.

`pg_file_write` writes the specified *data* into the file named by *filename*. If *append* is false, the file must not already exist. If *append* is true, the file can already exist, and will be appended to if so. Returns the number of bytes written.

`pg_file_sync` fsyncs the specified file or directory named by *filename*. An error is thrown on failure (e.g., the specified file is not present). Note that [data_sync_retry](#) has no effect on this function, and therefore a PANIC-level error will not be raised even on failure to flush database files.

`pg_file_rename` renames a file. If *archivename* is omitted or NULL, it simply renames *oldname* to *newname* (which must not already exist). If *archivename* is provided, it first renames *newname* to *archivename* (which must not already exist), and then renames *oldname* to *newname*. In event of failure of the second rename step, it will try to rename *archivename* back to *newname* before reporting the error. Returns true on success, false if the source file(s) are not present or not writable; other cases throw errors.

`pg_file_unlink` removes the specified file. Returns true on success, false if the specified file is not present or the `unlink()` call fails; other cases throw errors.

`pg_logdir_ls` returns the start timestamps and path names of all the log files in the [log_directory](#) directory. The [log_filename](#) parameter must have its default setting (`postgresql-%Y-%m-%d_%H%M%S.log`) to use this function.

F.2. amcheck — tools to verify table and index consistency

The `amcheck` module provides functions that allow you to verify the logical consistency of the structure of relations.

The B-Tree checking functions verify various *invariants* in the structure of the representation of particular relations. The correctness of the access method functions behind index scans and other important operations relies on these invariants always holding. For example, certain functions verify, among other things, that all B-Tree pages have items in “logical” order (e.g., for B-Tree indexes on `text`, index tuples should be in collated lexical order). If that particular invariant somehow fails to hold, we can expect binary searches on the affected page to incorrectly guide index scans, resulting in wrong answers to SQL queries. If the structure appears to be valid, no error is raised.

Verification is performed using the same procedures as those used by index scans themselves, which may be user-defined operator class code. For example, B-Tree index verification relies on comparisons made with one or more B-Tree support function 1 routines. See [Section 37.16.3](#) for details of operator class support functions.

Unlike the B-Tree checking functions which report corruption by raising errors, the heap checking function `verify_heapam` checks a table and attempts to return a set of rows, one row per corruption detected. Despite this, if facilities that `verify_heapam` relies upon are themselves corrupted, the function may be unable to continue and may instead raise an error.

Permission to execute `amcheck` functions may be granted to non-superusers, but before granting such permissions careful consideration should be given to data security and privacy concerns. Although the corruption reports generated by these functions do not focus on the contents of the corrupted data so much as on the structure of that data and the nature of the corruptions found, an attacker who gains permission to execute these functions, particularly if the attacker can also induce corruption, might be able to infer something of the data itself from such messages.

F.2.1. Functions

`bt_index_check(index regclass, heapallindexed boolean)` returns void

`bt_index_check` tests that its target, a B-Tree index, respects a variety of invariants. Example usage:

```
test=# SELECT bt_index_check(index => c.oid, heapallindexed => i.indisunique),
        c.relname,
        c.relpages
```

```
FROM pg_index i
JOIN pg_opclass op ON i.indclass[0] = op.oid
JOIN pg_am am ON op.opcmethod = am.oid
JOIN pg_class c ON i.indexrelid = c.oid
JOIN pg_namespace n ON c.relnamespace = n.oid
WHERE am.amname = 'btree' AND n.nspname = 'pg_catalog'
-- Don't check temp tables, which may be from another session:
AND c.relpersistence != 't'
-- Function may throw an error when this is omitted:
AND c.relkind = 'i' AND i.indisready AND i.indisvalid
ORDER BY c.relpages DESC LIMIT 10;
```

bt_index_check	relname	relpages
	pg_depend_reference_index	43
	pg_depend_depender_index	40
	pg_proc_proname_args_nsp_index	31
	pg_description_o_c_o_index	21
	pg_attribute_relid_attnam_index	14
	pg_proc_oid_index	10

Additional Supplied Modules
and Extensions Shipped in
postgrespro-std-16-contrib

pg_attribute_relid_attnum_index		9
pg_amproc_fam_proc_index		5
pg_amop_opr_fam_index		5
pg_amop_fam_strat_index		5

(10 rows)

This example shows a session that performs verification of the 10 largest catalog indexes in the database “test”. Verification of the presence of heap tuples as index tuples is requested for the subset that are unique indexes. Since no error is raised, all indexes tested appear to be logically consistent. Naturally, this query could easily be changed to call `bt_index_check` for every index in the database where verification is supported.

`bt_index_check` acquires an `AccessShareLock` on the target index and the heap relation it belongs to. This lock mode is the same lock mode acquired on relations by simple `SELECT` statements. `bt_index_check` does not verify invariants that span child/parent relationships, but will verify the presence of all heap tuples as index tuples within the index when *heapallindexed* is `true`. When a routine, lightweight test for corruption is required in a live production environment, using `bt_index_check` often provides the best trade-off between thoroughness of verification and limiting the impact on application performance and availability.

`bt_index_parent_check(index regclass, heapallindexed boolean, rootdescend boolean)` returns `void`

`bt_index_parent_check` tests that its target, a B-Tree index, respects a variety of invariants. Optionally, when the *heapallindexed* argument is `true`, the function verifies the presence of all heap tuples that should be found within the index. When the optional *rootdescend* argument is `true`, verification re-finds tuples on the leaf level by performing a new search from the root page for each tuple. The checks that can be performed by `bt_index_parent_check` are a superset of the checks that can be performed by `bt_index_check`. `bt_index_parent_check` can be thought of as a more thorough variant of `bt_index_check`: unlike `bt_index_check`, `bt_index_parent_check` also checks invariants that span parent/child relationships, including checking that there are no missing downlinks in the index structure. `bt_index_parent_check` follows the general convention of raising an error if it finds a logical inconsistency or other problem.

A `ShareLock` is required on the target index by `bt_index_parent_check` (a `ShareLock` is also acquired on the heap relation). These locks prevent concurrent data modification from `INSERT`, `UPDATE`, and `DELETE` commands. The locks also prevent the underlying relation from being concurrently processed by `VACUUM`, as well as all other utility commands. Note that the function holds locks only while running, not for the entire transaction.

`bt_index_parent_check`'s additional verification is more likely to detect various pathological cases. These cases may involve an incorrectly implemented B-Tree operator class used by the index that is checked, or, hypothetically, undiscovered bugs in the underlying B-Tree index access method code. Note that `bt_index_parent_check` cannot be used when hot standby mode is enabled (i.e., on read-only physical replicas), unlike `bt_index_check`.

Tip

`bt_index_check` and `bt_index_parent_check` both output log messages about the verification process at `DEBUG1` and `DEBUG2` severity levels. These messages provide detailed information about the verification process that may be of interest to PostgreSQL developers. Advanced users may also find this information helpful, since it provides additional context should verification actually detect an inconsistency. Running:

```
SET client_min_messages = DEBUG1;
```

in an interactive `psql` session before running a verification query will display messages about the progress of verification with a manageable level of detail.

`verify_heapam(relation regclass, on_error_stop boolean, check_toast boolean, skip text, startblock bigint, endblock bigint, blkno OUT bigint, offnum OUT integer, attnum OUT integer, msg OUT text)` returns setof record

Checks a table, sequence, or materialized view for structural corruption, where pages in the relation contain data that is invalidly formatted, and for logical corruption, where pages are structurally valid but inconsistent with the rest of the database cluster.

The following optional arguments are recognized:

`on_error_stop`

If true, corruption checking stops at the end of the first block in which any corruptions are found.

Defaults to false.

`check_toast`

If true, toasted values are checked against the target relation's TOAST table.

This option is known to be slow. Also, if the toast table or its index is corrupt, checking it against toast values could conceivably crash the server, although in many cases this would just produce an error.

Defaults to false.

`skip`

If not `none`, corruption checking skips blocks that are marked as all-visible or all-frozen, as specified. Valid options are `all-visible`, `all-frozen` and `none`.

Defaults to `none`.

`startblock`

If specified, corruption checking begins at the specified block, skipping all previous blocks. It is an error to specify a `startblock` outside the range of blocks in the target table.

By default, checking begins at the first block.

`endblock`

If specified, corruption checking ends at the specified block, skipping all remaining blocks. It is an error to specify an `endblock` outside the range of blocks in the target table.

By default, all blocks are checked.

For each corruption detected, `verify_heapam` returns a row with the following columns:

`blkno`

The number of the block containing the corrupt page.

`offnum`

The OffsetNumber of the corrupt tuple.

`attnum`

The attribute number of the corrupt column in the tuple, if the corruption is specific to a column and not the tuple as a whole.

`msg`

A message describing the problem detected.

F.2.2. Optional *heapallindexed* Verification

When the *heapallindexed* argument to B-Tree verification functions is `true`, an additional phase of verification is performed against the table associated with the target index relation. This consists of a “dummy” `CREATE INDEX` operation, which checks for the presence of all hypothetical new index tuples against a temporary, in-memory summarizing structure (this is built when needed during the basic first phase of verification). The summarizing structure “fingerprints” every tuple found within the target index. The high level principle behind *heapallindexed* verification is that a new index that is equivalent to the existing, target index must only have entries that can be found in the existing structure.

The additional *heapallindexed* phase adds significant overhead: verification will typically take several times longer. However, there is no change to the relation-level locks acquired when *heapallindexed* verification is performed.

The summarizing structure is bound in size by `maintenance_work_mem`. In order to ensure that there is no more than a 2% probability of failure to detect an inconsistency for each heap tuple that should be represented in the index, approximately 2 bytes of memory are needed per tuple. As less memory is made available per tuple, the probability of missing an inconsistency slowly increases. This approach limits the overhead of verification significantly, while only slightly reducing the probability of detecting a problem, especially for installations where verification is treated as a routine maintenance task. Any single absent or malformed tuple has a new opportunity to be detected with each new verification attempt.

F.2.3. Using *amcheck* Effectively

amcheck can be effective at detecting various types of failure modes that [data checksums](#) will fail to catch. These include:

- Structural inconsistencies caused by incorrect operator class implementations.

This includes issues caused by the comparison rules of operating system collations changing. Comparisons of datums of a collatable type like `text` must be immutable (just as all comparisons used for B-Tree index scans must be immutable), which implies that operating system collation rules must never change. Though rare, updates to operating system collation rules can cause these issues. More commonly, an inconsistency in the collation order between a primary server and a standby server is implicated, possibly because the *major* operating system version in use is inconsistent. Such inconsistencies will generally only arise on standby servers, and so can generally only be detected on standby servers.

If a problem like this arises, it may not affect each individual index that is ordered using an affected collation, simply because *indexed* values might happen to have the same absolute ordering regardless of the behavioral inconsistency. See [Section 22.1](#) and [Section 22.2](#) for further details about how Postgres Pro uses operating system locales and collations.

- Structural inconsistencies between indexes and the heap relations that are indexed (when *heapallindexed* verification is performed).

There is no cross-checking of indexes against their heap relation during normal operation. Symptoms of heap corruption can be subtle.

- Corruption caused by hypothetical undiscovered bugs in the underlying Postgres Pro access method code, sort code, or transaction management code.

Automatic verification of the structural integrity of indexes plays a role in the general testing of new or proposed Postgres Pro features that could plausibly allow a logical inconsistency to be introduced. Verification of table structure and associated visibility and transaction status information plays a similar role. One obvious testing strategy is to call *amcheck* functions continuously when running the standard regression tests.

- File system or storage subsystem faults where checksums happen to simply not be enabled.

Note that *amcheck* examines a page as represented in some shared memory buffer at the time of verification if there is only a shared buffer hit when accessing the block. Consequently, *amcheck*

does not necessarily examine data read from the file system at the time of verification. Note that when checksums are enabled, `amcheck` may raise an error due to a checksum failure when a corrupt block is read into a buffer.

- Corruption caused by faulty RAM, or the broader memory subsystem.

Postgres Pro does not protect against correctable memory errors and it is assumed you will operate using RAM that uses industry standard Error Correcting Codes (ECC) or better protection. However, ECC memory is typically only immune to single-bit errors, and should not be assumed to provide *absolute* protection against failures that result in memory corruption.

When `heapallindexed` verification is performed, there is generally a greatly increased chance of detecting single-bit errors, since strict binary equality is tested, and the indexed attributes within the heap are tested.

Structural corruption can happen due to faulty storage hardware, or relation files being overwritten or modified by unrelated software. This kind of corruption can also be detected with [data page checksums](#).

Relation pages which are correctly formatted, internally consistent, and correct relative to their own internal checksums may still contain logical corruption. As such, this kind of corruption cannot be detected with checksums. Examples include toasted values in the main table which lack a corresponding entry in the toast table, and tuples in the main table with a Transaction ID that is older than the oldest valid Transaction ID in the database or cluster.

Multiple causes of logical corruption have been observed in production systems, including bugs in the PostgreSQL server software, faulty and ill-conceived backup and restore tools, and user error.

Corrupt relations are most concerning in live production environments, precisely the same environments where high risk activities are least welcome. For this reason, `verify_heapam` has been designed to diagnose corruption without undue risk. It cannot guard against all causes of backend crashes, as even executing the calling query could be unsafe on a badly corrupted system. Access to [catalog tables](#) is performed and could be problematic if the catalogs themselves are corrupted.

In general, `amcheck` can only prove the presence of corruption; it cannot prove its absence.

F.2.4. Repairing Corruption

No error concerning corruption raised by `amcheck` should ever be a false positive. `amcheck` raises errors in the event of conditions that, by definition, should never happen, and so careful analysis of `amcheck` errors is often required.

There is no general method of repairing problems that `amcheck` detects. An explanation for the root cause of an invariant violation should be sought. [pageinspect](#) may play a useful role in diagnosing corruption that `amcheck` detects. A `REINDEX` may not be effective in repairing corruption.

F.3. aqo — cost-based query optimization

The aqo module is a Postgres Pro Standard extension for cost-based query optimization. Using machine learning methods, more precisely, a modification of the k-NN algorithm, aqo improves cardinality estimation, which can optimize execution plans and, consequently, speed up query execution.

F.3.1. Description

The aqo module can collect statistics on all the executed queries, excluding the queries that access system relations. The collected statistics is classified by query class. If the queries differ in their constants only, they belong to the same class. For each query class, aqo stores the cardinality quality, planning time, execution time, and execution statistics for machine learning. Based on this data, aqo builds a new query plan and uses it for the next query of the same class. aqo test runs have shown significant performance improvements for complex queries.

aqo saves all the learning data ([aqo_data](#)), queries ([aqo_query_texts](#)), query settings ([aqo_queries](#)), and query execution statistics ([aqo_query_stat](#)) to files. When aqo starts, it loads this data to shared memory. You can access aqo data through functions and views.

When [aqo.advanced](#) is on, and aqo is run in the `intelligent` or `learn` mode, a unique hash value, which is computed from the query tree, is assigned to each query class to identify it and separate the collected statistics. If `aqo.advanced` is off, the statistics for all untracked query classes is stored in a common query class with hash 0.

Each query class has an associated separate space, called *feature space*, in which the statistics for this query class is collected. This feature space is identified by a hash value (`fs`), which is usually the same as the query ID. Each feature space has associated *feature subspaces*, where the information about selectivity and cardinality for each query plan node is collected. Each subspace is also identified by a hash value (`fss`).

Query-specific optimization settings are stored in the [aqo_queries](#) view.

F.3.1.1. Limitations

aqo currently has the following limitations:

- Query optimization using the aqo module is not supported on standby.
- Query optimization with aqo does not work with queries that only have temporary objects.
- Query optimization with aqo does not work for queries that contain `IMMUTABLE` functions.
- aqo does not collect statistics on replicas because replicas are read-only. However, aqo may use query execution statistics from the primary if the replica is physical.
- `learn` and `intelligent` modes are not supposed to work for a whole cluster with queries having a dynamically generated structure because these modes store all query class IDs, which are different for all queries in such a workload. Dynamically generated constants are supported, however.

F.3.2. Installation and Setup

The aqo extension is included into Postgres Pro Standard. Once you have Postgres Pro Standard installed, complete the following steps to enable aqo:

1. Add aqo to the [shared_preload_libraries](#) parameter in the `postgresql.conf` file:

```
shared_preload_libraries = 'aqo'
```

The aqo library must be preloaded at the server startup, since adaptive query optimization needs to be enabled per cluster.

2. Create the aqo extension using the following query:

```
CREATE EXTENSION aqo;
```

Once the extension is created, you can start optimizing queries.

To disable aqo in the current database, run:

```
DROP EXTENSION aqo;
```

To disable aqo at the cluster level, run:

```
ALTER SYSTEM SET aqo.enable = off;  
SELECT pg_reload_conf();
```

To remove all the aqo data including the collected statistics, call `aqo_reset()`: to remove the data from the current database, run:

```
SELECT aqo_reset();
```

to remove all the data from the aqo storage, run:

```
SELECT aqo_reset(NULL);
```

If you do not want aqo to be loaded at the server restart, remove the line

```
shared_preload_libraries = 'aqo'
```

from the `postgresql.conf` file.

Important

For smooth physical replication transferring aqo data from the primary to a replica, ensure that the same aqo versions are installed on both. You can have different aqo versions installed, but in this case, set `aqo.wal_rw` to `off` on both and anticipate no replication.

F.3.2.1. Configuration

aqo behavior mainly depends on the `aqo.enable`, `aqo.mode` and `aqo.advanced` configuration parameters. Their default values allow you to start learning in the `aqo basic mode` once you just set `aqo.enable` to `on`.

To dynamically change any of these parameters, for example, `mode`, in your current session, run the following command:

```
SET aqo.mode = 'mode';
```

where *mode* is the name of the operation mode to use.

F.3.3. Usage

F.3.3.1. Using aqo in a Basic Mode

By default, `aqo.advanced` is off. This sets a recommended, basic, mode, where statistics is collected for plan nodes (identified by `fs`), and the collected machine learning data is used to correct the cardinality error for all queries whose plan contains a certain plan node. Once you set `aqo.enable` to `on`, aqo starts learning. Execute queries that you need to optimize several times until the plan is good enough and change `aqo.mode` to `frozen`. To apply the machine learning data at the level of the server instance, run the following command:

```
ALTER SYSTEM SET aqo.mode = frozen;  
ALTER SYSTEM SET aqo.enable = on;  
SELECT pg_reload_conf();
```

The machine learning data will be applied not only to the queries on which aqo learned, but to all the queries whose plan contains the nodes for which the statistics was collected. For the machine learning data not affect other queries, set `aqo.advanced` to `on` and collect statistics for individual queries. See [Section F.3.3.2](#) for details.

F.3.3.2. Choosing the Operation Mode for Advanced Query Optimization

If you often run queries of the same class, for example, your application limits the number of possible query classes, you can enable `aqo.advanced` and use the `intelligent` mode to improve planning for these queries. In this mode, aqo analyzes each query execution and stores statistics. Statistics on queries of different classes is stored separately. If performance is not improved after 50 iterations, the aqo extension falls back to the default query planner.

Note

You can view the current query plan using the standard Postgres Pro `EXPLAIN` command with the `ANALYZE` option. For details, see the [Section 14.1](#).

Since the `intelligent` mode tries to learn separately for different query classes, `aqo` may fail to provide performance improvements if queries in the workload are of multiple different classes or if the classes of the queries in the workload are constantly changing. For such workloads, reset the `aqo` extension to the `controlled` mode, or try to turn off `aqo.advanced`.

When `aqo.advanced` is on, in the `controlled` mode, `aqo` does not collect statistics for new query classes, so they will not be optimized, but for known query classes, `aqo` will continue collecting statistics and using optimized planning algorithms. So use the `controlled` mode only after `aqo` learned in the `learn` or `intelligent` mode.

After `aqo` has already learned, `controlled` is the mode recommended for production use. To make `aqo` run in this mode on your whole production cluster, run

```
ALTER SYSTEM SET aqo.mode = 'controlled';
SELECT pg_reload_conf();
```

When `aqo.advanced` is on, the `learn` mode collects statistics from all the executed queries and updates the data for query classes. This mode is similar to the `intelligent` mode, except that it does not provide intelligent tuning. This mode is not recommended to be used permanently for a whole cluster because it tries `aqo` optimizations for every query class, even for those that do not need it, and this may lead to an unnecessary computational overhead and cause performance degradation.

Use the `learn` mode with `aqo.advanced` turned off to handle workloads with dynamically generated query structures. Overall performance improvement is not guaranteed. As this mode lacks intelligent tuning, the performance for some queries may even decrease, but this mode is good for a dynamic workload and consumes less memory than the `intelligent` mode.

If you want to reduce the impact of `aqo` on query planning and execution, you can use it in the `frozen` mode. In this mode, `aqo` only reads the collected statistics, but does not collect any new data.

F.3.3.3. Fine-Tuning aqo

You must have superuser rights to access `aqo` views and configure advanced query settings.

You can view all the processed query classes and their corresponding hash values in the [aqo_query_texts](#) view:

```
SELECT * FROM aqo_query_texts;
```

To find out the class, that is, hash, of a query and `aqo` mode, enable [aqo.show_hash \(boolean\)](#) (boolean) and [aqo.show_details \(boolean\)](#) (boolean) environment variables and execute the query. The output will contain something like this:

```
...
Planning Time: 23.538 ms
...
Execution Time: 249813.875 ms
...
Using aqo: true
AQO mode: LEARN
AQO advanced: OFF
...
Query hash: -2439501042637610315
```

Each query class has its own optimization settings. These settings are shown in the [aqo_queries](#) view:

```
SELECT * FROM aqo_queries;
```

You can manually change these settings to adjust the optimization for a particular query class. For example:

```
-- Add a new query class to the aqo_queries view:

SET aqo.advanced='on';
SET aqo.mode='intelligent';
SELECT * FROM a, b WHERE a.id=b.id;
SET aqo.mode='controlled';

-- Disable auto_tuning, enable both learn_aqo and use_aqo
-- for this query class:

SELECT count(*) FROM aqo_queries,
  LATERAL aqo_queries_update(queryid, NULL, NULL, true, true, false)
WHERE queryid = (SELECT queryid FROM aqo_query_texts
WHERE query_text LIKE 'SELECT * FROM a, b WHERE a.id=b.id;');

-- Run EXPLAIN ANALYZE while the plan changes:

EXPLAIN ANALYZE SELECT * FROM a, b WHERE a.id=b.id;
EXPLAIN ANALYZE SELECT * FROM a, b WHERE a.id=b.id;

-- Disable learning to stop statistics collection
-- and use the optimized plan:

SELECT count(*) FROM aqo_queries,
  LATERAL aqo_queries_update(queryid, NULL, NULL, false, true, false)
WHERE queryid = (SELECT queryid FROM aqo_query_texts
WHERE query_text LIKE 'SELECT * FROM a, b WHERE a.id=b.id;');
```

To stop intelligent tuning for a particular query class, disable the `auto_tuning` setting:

```
SELECT count(*) FROM aqo_queries,
  LATERAL aqo_queries_update(queryid, NULL, NULL, NULL, NULL, false)
WHERE queryid = 'hash';
```

where *hash* is the hash value for this query class. As a result, aqo disables automatic change of the `learn_aqo` and `use_aqo` settings.

To disable further learning for a particular query class, use the following command:

```
SELECT count(*) FROM aqo_queries,
  LATERAL aqo_queries_update(queryid, NULL, NULL, false, NULL, false)
WHERE queryid = 'hash';
```

where *hash* is the hash value for this query class.

To fully disable aqo for all queries and use the default Postgres Pro query planner, run:

```
SELECT count(*) FROM aqo_queries,
  LATERAL aqo_disable_class(queryid, NULL)
WHERE queryid <> 0;
```

To disable aqo for all queries temporarily in the current session or for the whole cluster, but not remove or change the collected statistics and settings, turn off [aqo.enable](#):

```
SET aqo.enable = 'off';

or

ALTER SYSTEM SET aqo.enable = 'off'
```

F.3.3.4. Sandbox Mode

You can experiment with aqo without touching its main knowledge base. To do this, execute the command `SET aqo.sandbox = ON;`

This turns on the *sandbox mode*, which means that aqo will work in the isolated environment. However, if you turn on [aqo.sandbox](#) in different SQL sessions, they will use the same data.

Data obtained in the sandbox mode does not get replicated. But the sandbox mode can be used on a standby. Moreover, the only way to train aqo on a standby is turning on the sandbox mode when the replication is turned on, that is, `aqo.wal_rw` is true. Without the sandbox mode, aqo will work on the standby as if `aqo.mode = FROZEN`, that is, it will be able to use the existing knowledge base, but not update or extend it.

F.3.4. Reference

F.3.4.1. Configuration Parameters

`aqo.enable` (boolean)

Defines the state of aqo. If set to `off` aqo does not work except when [aqo.force_collect_stat](#) = `on`.

Default: `off`.

`aqo.mode` (text)

Sets the aqo operation mode. Defines how aqo handles new queries. Possible values:

- `intelligent` — saves new queries with `auto_tuning` enabled. See the description of the [aqo_queries](#) view for more details. May disable aqo for a query in the case of average performance reduction. Only works in this way if [aqo.advanced](#) = `on`, otherwise, this mode works exactly like `learn`.
- `learn` — collects statistics on all the executed queries, learns and makes predictions based on these statistics.
- `controlled` — only learns and makes predictions for known queries.
- `frozen` — makes predictions for known queries, but does not learn from any queries.

Default: `learn`.

`aqo.advanced` (boolean)

Enables the advanced learning routine, which saves separate learning statistics for each query class. Also allows fine-tuning the `use_aqo` and `learn_aqo` settings in the [aqo_queries](#) view. Fine-tuned query settings in the `aqo_query` view continue to work if `aqo.advanced` is disabled.

Default: `off`.

`aqo.force_collect_stat` (boolean)

Collects statistics on query executions in all aqo modes and even if `aqo.enable` is `off`.

Default: `off`.

`aqo.show_details` (boolean)

Adds some details to `EXPLAIN` output of a query, such as the prediction or feature-subspace hash, and shows some additional aqo-specific on-screen information.

Default: `on`.

`aqo.show_hash` (boolean)

Shows a hash value that uniquely identifies the class of queries or class of plan nodes. aqo uses the native query ID to identify a query class for consistency with other extensions, such as [pg_stat_statements](#). So, the query ID can be taken from the `Query hash` field in `EXPLAIN ANALYZE` output of a query.

Default: on.

`aqo.join_threshold (integer)`

Ignores queries that contain smaller number of joins, which means that statistics for such queries is not collected.

Default: 0 (no queries are ignored).

`aqo.learn_statement_timeout (boolean)`

Learns on a plan interrupted by the statement timeout.

Default: off.

`aqo.statement_timeout (integer)`

Defines the initial value of the *smart statement timeout*, in milliseconds, which is needed to limit the execution time when manually training aqo on special queries with a poor cardinality forecast. aqo can dynamically change the value of the smart statement timeout during this training. When the cardinality estimation error on nodes exceeds 0.1, the value of `aqo.statement_timeout` is automatically incremented exponentially, but remains not greater than [statement_timeout](#).

Default: 0.

`aqo.wide_search (boolean)`

Enables searching neighbors with the same feature subspace among different query classes. Only has an effect if [aqo.advanced](#) = on.

Default: off.

`aqo.min_neighbors_for_predicting (integer)`

Defines how many samples collected in previous executions of the query will be used to predict the cardinality next time. If there are fewer of them, aqo will not make any prediction. A too large value may affect performance, but a too small value may reduce the prediction quality.

Default: 3.

`aqo.predict_with_few_neighbors (boolean)`

Enables aqo to make predictions with fewer neighbors than specified by [aqo.min_neighbors_for_predicting](#). When set to off, then aqo learns, but does not make predictions until the execution count for the query with different constants reaches 3 (default for `aqo.min_neighbors_for_predicting`).

Default: on.

`aqo.fs_max_items (integer)`

Defines the maximum number of feature spaces that aqo can operate with. When this number is exceeded, learning on new query classes will no longer occur, and they will not appear in the views accordingly. This parameter can only be set at server start.

Default: 10000.

`aqo.fss_max_items (integer)`

Defines the maximum number of feature subspaces that aqo can operate with. When this number is exceeded, the selectivity and cardinality for new query plan nodes will no longer be collected, and new feature subspaces will not appear in the [aqo_data](#) view accordingly. This parameter can only be set at server start.

Default: 100000.

`aqo.querytext_max_size` (integer)

Defines the maximum size of the query in the [aqo_query_texts](#) view. This parameter can only be set at server start.

Default: 1000.

`aqo.dsm_size_max` (integer)

Defines the maximum size of dynamic shared memory, in MB, that aqo can allocate to store learning data and query texts. If set to a number that is less than the size of the saved aqo data, the server will not start. This parameter can only be set at server start.

Default: 100.

`aqo.wal_rw` (boolean)

Enables physical replication and allows complete aqo data recovery after failure. When set to `off` on the primary, no data is transferred from it to a replica. When set to `off` on a replica, any data transferred from the primary is ignored. With this value, when the server fails, data can only be restored as of the last checkpoint. This parameter can only be set at server start.

Default: `on`.

`aqo.sandbox` (boolean)

Enables reserving a separate memory area in shared memory to be used by a primary or standby node, which allows collecting and using statistics with the data in this memory area. If enabled on the primary, the extension uses the separate shared memory area that is not replicated to the standby. Changing the value of this parameter resets the aqo cache. Only superusers can change this setting.

Default: `off`.

F.3.4.2. Views

F.3.4.2.1. `aqo_query_texts`

The `aqo_query_texts` view classifies all the query classes processed by aqo. For each query class, the view shows the text of the first analyzed query of this class.

Table F.2. `aqo_query_texts` View

Column Name	Description
<code>queryid</code>	The unique identifier of the query class.
<code>dbid</code>	The identifier of the database.
<code>query_text</code>	Text of the first analyzed query of the given class. The query text length is limited by aqo.querytext_max_size .

F.3.4.2.2. `aqo_queries`

The `aqo_queries` view shows optimization settings for different query classes. One query executed in two different databases is stored twice although the `queryid` is the same.

Table F.3. `aqo_queries` View

Setting	Description
<code>queryid</code>	The unique identifier of the query class.
<code>dbid</code>	The identifier of the database in which the query was executed.
<code>fs</code>	The unique identifier (hash) of the feature space in which the statistics for this query class is collected. Defaults to <code>queryid</code> . You can manually set

Setting	Description
	<code>fs</code> to the same value for different query classes, especially for similar queries.
<code>learn_aqo</code>	Shows whether statistics collection for this query class is enabled.
<code>use_aqo</code>	Shows whether the aqo cardinality prediction for the next execution of this query class is enabled.
<code>auto_tuning</code>	Shows whether aqo can dynamically change <code>use_aqo</code> and <code>learn_aqo</code> settings for this query class. By default, set to <code>true</code> for new queries if <code>aqo.advanced</code> is on and <code>aqo.mode</code> = <code>intelligent</code>. When <code>auto_tuning</code> is on, if for several successive executions of a query for which <code>use_aqo</code> is off, the cardinality error remains sufficiently small and stable, aqo turns on <code>use_aqo</code>. For queries with <code>learn_aqo</code> = <code>true</code> (it is so for new queries), several first executions are done both using aqo and without it. The faster the query is executed compared to the execution with the standard planner, the more likely aqo will be used for the next query execution. If after a certain number of executions the execution time with aqo appears to be worse than with the standard planner, aqo will never be used for this query class: <code>auto_tuning</code>, <code>use_aqo</code> and <code>learn_aqo</code> are set to <code>off</code>.
<code>smart_timeout</code>	The value of the smart statement timeout for this query class. The initial value of the smart statement timeout for any query is defined by the <code>statement_timeout</code> configuration parameter.
<code>count_increase_timeout</code>	Shows how many times the smart statement timeout increased for this query class.

F.3.4.2.3. aqo_data

The `aqo_data` view shows machine learning data for cardinality estimation refinement. The number of rows is limited by `aqo.fss_max_items`. To discard all the collected statistics for a particular query class, you can delete all rows from `aqo_data` with the corresponding `fs`.

Table F.4. aqo_data View

Data	Description
<code>fs</code>	The identifier (hash) of the feature space.
<code>fss</code>	The identifier (hash) of the feature subspace.
<code>dbid</code>	The identifier of the database.
<code>nfeatures</code>	Feature-subspace size for the query plan node.
<code>features</code>	Logarithm of the selectivity which the cardinality prediction is based on.
<code>targets</code>	Cardinality logarithm for the query plan node.
<code>reliability</code>	Confidence level of the learning statistics. Equals: 1 (default) — indicates data obtained after normal execution of a query

Data	Description
	0.1 — indicates data obtained from a partially executed node (not needed as unreliable) 0.9 — indicates data obtained from a finished node, but from a partially executed statement
oids	List of IDs of tables that were involved in the prediction for this node.
tmpoids	List of IDs of temporary tables that were involved in the prediction for this node.

F.3.4.2.4. aqo_query_stat

The `aqo_query_stat` view shows statistics on query execution, by query class. `aqo` uses this data when `auto_tuning` is enabled for a particular query class.

Table F.5. `aqo_query_stat` View

Data	Description
queryid	The unique identifier of the query class.
dbid	The identifier of the database.
execution_time_with_aqo	Array of execution times for queries run with <code>aqo</code> enabled.
execution_time_without_aqo	Array of execution times for queries run with <code>aqo</code> disabled.
planning_time_with_aqo	Array of planning times for queries run with <code>aqo</code> enabled.
planning_time_without_aqo	Array of planning times for queries run with <code>aqo</code> disabled.
cardinality_error_with_aqo	Array of cardinality estimation errors in the selected query plans with <code>aqo</code> enabled.
cardinality_error_without_aqo	Array of cardinality estimation errors in the selected query plans with <code>aqo</code> disabled.
executions_with_aqo	Number of queries run with <code>aqo</code> enabled.
executions_without_aqo	Number of queries run with <code>aqo</code> disabled.

F.3.4.3. Functions

`aqo` adds several functions to Postgres Pro catalog.

F.3.4.3.1. Storage Management Functions

Important

Functions `aqo_queries_update`, `aqo_query_texts_update`, `aqo_query_stat_update`, `aqo_data_update` and `aqo_data_delete` modify data files underlying `aqo` views. Therefore, call these functions only if you understand the logic of adaptive query optimization.

`aqo_cleanup()` → setof integer

Removes data related to query classes that are linked (may be partially) with removed relations. Returns the number of removed feature spaces (classes) and feature subspaces. Insensitive to removing other objects.

`aqo_enable_class (queryid bigint, dbid oid) → void`

Sets `learn_aqo`, `use_aqo` and `auto_tuning` (only in the intelligent mode) to true for the query class with the specified `queryid` and `dbid`. You can set `dbid` to NULL instead of the ID of the current database.

`aqo_disable_class (queryid bigint, dbid oid) → void`

Sets `learn_aqo`, `use_aqo` and `auto_tuning` to false for the query class with the specified `queryid` and `dbid`. You can set `dbid` to NULL instead of the ID of the current database.

`aqo_drop_class (queryid bigint, dbid oid) → integer`

Removes all data related to the specified query class and database from the aqo storage. You can set `dbid` to NULL instead of the ID of the current database. Returns the number of records removed from the aqo storage.

`aqo_reset (dbid oid) → bigint`

Removes records from the specified database: machine learning data, query texts, statistics and query class preferences. If `dbid` is omitted, removes the data from the current database. If `dbid` is NULL, removes all records from the aqo storage. Returns the number of records removed.

`aqo_queries_update (queryid bigint, dbid oid, fs bigint, learn_aqo boolean, use_aqo boolean, auto_tuning boolean) → boolean`

Updates or inserts a record in a data file underlying the [aqo_queries](#) view for the specified `queryid` and `dbid`. You can set `dbid` to NULL instead of the ID of the current database. NULL values for parameters being set mean leave them as is. Note that records with a zero value of `queryid` or `dbid` cannot be updated. Returns `false` in case of error, `true` otherwise.

`aqo_query_texts_update (queryid bigint, dbid oid, query_text text) → boolean`

Updates or inserts a record in a data file underlying the [aqo_query_texts](#) view for the specified `queryid` and `dbid`. You can set `dbid` to NULL instead of the ID of the current database. Note that records with a zero value of `queryid` or `dbid` cannot be updated. Returns `false` in case of error, `true` otherwise.

`aqo_query_stat_update (queryid bigint, dbid oid, execution_time_with_aqo double precision[], execution_time_without_aqo double precision[], planning_time_with_aqo double precision[], planning_time_without_aqo double precision[], cardinality_error_with_aqo double precision[], cardinality_error_without_aqo double precision[], executions_with_aqo bigint[], executions_without_aqo bigint[]) → boolean`

Updates or inserts a record in a data file underlying the [aqo_query_stat](#) view for the specified `queryid` and `dbid`. You can set `dbid` to NULL instead of the ID of the current database. Returns `false` in case of error, `true` otherwise.

`aqo_data_update (fs bigint, fss integer, dbid oid, nfeatures integer, features double precision[][], targets double precision[], reliability double precision[], oids oid[], tmpoids oid[]) → boolean`

Updates or inserts a record in a data file underlying the [aqo_data](#) view for the specified `fs`, `fss` and `dbid`. You can set `dbid` to NULL instead of the ID of the current database. Returns `false` in case of error, `true` otherwise.

`aqo_data_delete (fs bigint, fss integer, dbid oid) → boolean`

Removes a record from a data file underlying the [aqo_data](#) view for the specified `fs`, `fss` and `dbid`. You can set `dbid` to NULL instead of the ID of the current database. Returns `false` in case of error, `true` otherwise.

F.3.4.3.2. Memory Management Functions

`aqo_memory_usage ()` $\rightarrow$ `setof record`

Shows allocated and used sizes of aqo memory contexts and hash tables. Returns a table:

`name`

Short description of the memory context or hash table

`allocated_size`

Total size of the allocated memory

`used_size`

Size of the currently used memory

F.3.4.3.3. Functions for Analytics

`aqo_cardinality_error (controlled boolean)` $\rightarrow$ `setof record`

Shows the cardinality error for the last execution of queries. If *controlled* is true, shows queries executed with aqo enabled. If *controlled* is false, shows queries that were executed with aqo disabled, but that have collected aqo statistics. Returns a table:

`num`

Sequential number

`queryid`

The unique identifier of the query class

`dbid`

The identifier of the database

`fs`

The identifier of the feature space, usually zero or `queryid`

`error`

aqo error calculated on query plan nodes

`nexecs`

Number of executions of queries associated with this `queryid`

`aqo_execution_time (controlled boolean)` $\rightarrow$ `setof record`

Shows the execution time for queries. If *controlled* is true, shows the execution time of the last execution with aqo enabled. If *controlled* is false, returns the average execution time for all logged executions with aqo disabled. Execution time without aqo can be collected when `aqo.mode = intelligent` or `aqo.force_collect_stat = on`. Returns a table:

`num`

Sequential number

`queryid`

The unique identifier of the query class

dbid

The identifier of the database

fs

The identifier of the feature space, usually zero or queryid

exec_time

If *controlled* = true, last query execution time with aqo, otherwise, average execution time for all executions without aqo

nexecs

Number of executions of queries associated with this queryid

F.3.5. Examples

Example F.1. Learning on a Query (Basic Mode)

Consider optimization of a query using aqo.

When the query is executed for the first time, it is missing in tables underlying aqo views. So there is no data for predicting with aqo for each plan node, and “AQO not used” lines appear in the `EXPLAIN` output:

```
demo=# EXPLAIN (ANALYZE, SUMMARY OFF, TIMING OFF)
SELECT bp.*
FROM ticket_flights tf
JOIN flights f ON f.flight_id = tf.flight_id
JOIN boarding_passes bp ON bp.ticket_no = tf.ticket_no AND bp.flight_id = tf.flight_id
WHERE f.scheduled_departure > '2017-08-15 15:00:00+00';
QUERY PLAN
-----
Hash Join  (cost=63796.33..140286.73 rows=477728 width=25) (actual rows=2215 loops=1)
  AQO not used, fss=8598194613120045129
  Hash Cond: ((bp.flight_id = f.flight_id) AND (bp.ticket_no = tf.ticket_no))
    -> Seq Scan on boarding_passes bp  (cost=0.00..32894.95 rows=1894295 width=25)
        (actual rows=1894295 loops=1)
        AQO not used, fss=1362775811343989307
        -> Hash  (cost=51379.43..51379.43 rows=595260 width=22) (actual rows=468255
            loops=1)

```

If there is no information on a certain node in the `aqo_data` view, aqo will add the appropriate record there for future learning and predictions except for nodes with `fss=0` in the `EXPLAIN` output. As each of features and targets in the `aqo_data` view is a logarithm to base e , to get the actual value, raise e to this power. For example: `exp(7.703007682479236)`:

```
demo=# select * from aqo_data;
 fs |          fss          | dbid | nfeatures |          features
----+-----+-----+-----+-----+-----+-----

                                        Rows Removed by Filter: 46624

Using aqp: true
AQO mode: LEARN
AQO advanced: OFF
Query hash: 402936317627943257
JOINS: 2
(23 rows)
```

However, instead of recalculating features and targets, aqo added new values of selectivity and cardinality for this query to aqo_data:

```
demo=# select * from aqo_data;
 fs |          fss          | dbid | nfeatures |          targets          |
 features | reliability |          oids          | tmpoids |
-----+-----+-----+-----+-----
+-----+-----+-----+-----+-----
+-----+-----+-----+-----+-----
+-----+-----+-----+-----+-----
 0 | 1362775811343989307 | 16429 |          0 | | {14.454357295615447}
  | {1}          | {16452}          |          |
 0 | -6410966714754547713 | 16429 |          0 | | {14.674314116080508}
  | {1}          | {16479}          |          |
 0 | -1289471166524579716 | 16429 |          1 | | {-1.3775704575284085},
{-1.2287385463463019}}
{9.701371368413994,9.854297308345357} | {1,1}          | {16458}          |
 0 | 8598194613120045129 | 16429 |          2 | |
{-13.492416828684513,-1.3775704575284085},{-13.492416828684513,-1.2287385463463019}}
| {7.703007682479236,11.620855676130656} | {1,1}          | {16479,16458,16452} |
 0 | -7651474063207585780 | 16429 |          2 | |
{-11.092306109090387,-1.3775704575284085},{-11.092306109090387,-1.2287385463463019}}
| {13.056768298305919,13.266354624518149} | {1,1}          | {16479,16458}          |
(5 rows)
```

Now the prediction has a small error of about 3%, which can be explained by a calculation error:

```
demo=# EXPLAIN (ANALYZE, SUMMARY OFF, TIMING OFF)
SELECT bp.*
FROM ticket_flights tf
JOIN flights f ON f.flight_id = tf.flight_id
JOIN boarding_passes bp ON bp.ticket_no = tf.ticket_no AND bp.flight_id = tf.flight_id
WHERE f.scheduled_departure > '2017-08-10 15:00:00+00';
                                QUERY PLAN

Example F.2. Using the `aqo_query_stat` View

The `aqo_query_stats` view shows statistics on the query planning time, query execution time and cardinality error. Based on this data you can make a decision whether to use aqo predictions for different query classes.

Let's query the `aqo_query_stats` view:

```
demo=# SELECT * FROM aqo_query_stat \gx
-[ RECORD 1 ]-----
+-----+
queryid          | 7809046947949890015
dbid             | 16429
execution_time_with_aqo | {1.039218233,0.925258453,0.831166925,0.779602353}
execution_time_without_aqo | {1.022052611,0.936486619}
planning_time_with_aqo | {0.003305339,0.002129048,0.002538877,0.002142972}
planning_time_without_aqo | {0.000767553,0.000711208}
cardinality_error_with_aqo | 
{0.4854215265638894,0,1.1711726076352047,0.007732205169478082}
cardinality_error_without_aqo | {0.4854215265638894,1.571562511977072}
executions_with_aqo | 4
executions_without_aqo | 2
```

The retrieved data is for the query from [Example F.1](#), which was executed once without aqo for each of the parameters `f.scheduled_departure > '2017-08-10 15:00:00+00'` and `f.scheduled_departure > '2017-08-15 15:00:00+00'` and twice with aqo for each of these parameters. It is clear that with aqo, the cardinality error decreases to 0.0077, while the minimum cardinality error without aqo is 0.4854. Besides, the execution time with aqo is lower than without it. So the conclusion is that aqo learns well on this query, and the prediction can be used for this query class.

Example F.3. Using aqo in the Advanced Mode

The advanced mode allows a more flexible control over aqo. When this mode is activated, that is,

```
demo=# SET aqo.advanced = on;
```

aqo will collect the machine learning data separately for each query executed. For example:

```
demo=# EXPLAIN (ANALYZE, SUMMARY OFF, TIMING OFF)
SELECT bp.*
FROM ticket_flights tf
JOIN flights f ON f.flight_id = tf.flight_id
JOIN boarding_passes bp ON bp.ticket_no = tf.ticket_no AND bp.flight_id = tf.flight_id
WHERE f.scheduled_departure > '2017-08-15 15:00:00+00';
                                QUERY PLAN
-----

{16479,16458}          |          |          |          |          |
(5 rows)

```

We can make a few settings individually for this query. These are values of `learn_aqo`, `use_aqo` and `auto_tuning` in the [aqo_queries](#) view:

```

demo=# SELECT * FROM aqo_queries;
      queryid      | dbid |          fs          | learn_aqo | use_aqo | auto_tuning |
smart_timeout | count_increase_timeout
-----+-----+-----+-----+-----+-----+
+-----+-----+-----+-----+-----+-----+
402936317627943257 | 16429 | 402936317627943257 | t          | t          | f          |
          0 |          0 |          0 |          0 | f          | f          | f          |
          0 |          0 |          0 |          0 |          0 | f          | f          |
(2 rows)

```

Let's set `use_aqo` to false:

Additional Supplied Modules
and Extensions Shipped in
postgrespro-std-16-contrib

```
demo=# SELECT aqo_queries_update(402936317627943257, NULL, NULL, NULL, false, NULL);
 aqo_queries_update
-----
 t
(1 row)
```

Now we change a constant in the query:

```
demo=# EXPLAIN (ANALYZE, SUMMARY OFF, TIMING OFF)
SELECT bp.*
FROM ticket_flights tf
JOIN flights f ON f.flight_id = tf.flight_id
JOIN boarding_passes bp ON bp.ticket_no = tf.ticket_no AND bp.flight_id = tf.flight_id
WHERE f.scheduled_departure > '2017-08-10 15:00:00+00';
                                QUERY PLAN

FROM aqo_data_sandbox WHERE fs = 0;  
DROP TABLE aqo_data_sandbox;
```

F.3.6. Author

Oleg Ivanov

F.4. auth_delay — pause on authentication failure

`auth_delay` causes the server to pause briefly before reporting authentication failure, to make brute-force attacks on database passwords more difficult. Note that it does nothing to prevent denial-of-service attacks, and may even exacerbate them, since processes that are waiting before reporting authentication failure will still consume connection slots.

In order to function, this module must be loaded via [shared_preload_libraries](#) in `postgresql.conf`.

F.4.1. Configuration Parameters

`auth_delay.milliseconds` (integer)

The number of milliseconds to wait before reporting an authentication failure. The default is 0.

These parameters must be set in `postgresql.conf`. Typical usage might be:

```
# postgresql.conf
shared_preload_libraries = 'auth_delay'

auth_delay.milliseconds = '500'
```

F.4.2. Author

KaiGai Kohei <kaigai@ak.jp.nec.com>

F.5. auto_explain — log execution plans of slow queries

The `auto_explain` module provides a means for logging execution plans of slow statements automatically, without having to run `EXPLAIN` by hand. This is especially helpful for tracking down un-optimized queries in large applications.

The module provides no SQL-accessible functions. To use it, simply load it into the server. You can load it into an individual session:

```
LOAD 'auto_explain';
```

(You must be superuser to do that.) More typical usage is to preload it into some or all sessions by including `auto_explain` in `session_preload_libraries` or `shared_preload_libraries` in `postgresql.conf`. Then you can track unexpectedly slow queries no matter when they happen. Of course there is a price in overhead for that.

F.5.1. Configuration Parameters

There are several configuration parameters that control the behavior of `auto_explain`. Note that the default behavior is to do nothing, so you must set at least `auto_explain.log_min_duration` if you want any results.

`auto_explain.log_min_duration (integer)`

`auto_explain.log_min_duration` is the minimum statement execution time, in milliseconds, that will cause the statement's plan to be logged. Setting this to 0 logs all plans. -1 (the default) disables logging of plans. For example, if you set it to 250ms then all statements that run 250ms or longer will be logged. Only superusers can change this setting.

`auto_explain.log_parameter_max_length (integer)`

`auto_explain.log_parameter_max_length` controls the logging of query parameter values. A value of -1 (the default) logs the parameter values in full. 0 disables logging of parameter values. A value greater than zero truncates each parameter value to that many bytes. Only superusers can change this setting.

`auto_explain.log_analyze (boolean)`

`auto_explain.log_analyze` causes `EXPLAIN ANALYZE` output, rather than just `EXPLAIN` output, to be printed when an execution plan is logged. This parameter is off by default. Only superusers can change this setting.

Note

When this parameter is on, per-plan-node timing occurs for all statements executed, whether or not they run long enough to actually get logged. This can have an extremely negative impact on performance. Turning off `auto_explain.log_timing` ameliorates the performance cost, at the price of obtaining less information.

`auto_explain.log_buffers (boolean)`

`auto_explain.log_buffers` controls whether buffer usage statistics are printed when an execution plan is logged; it's equivalent to the `BUFFERS` option of `EXPLAIN`. This parameter has no effect unless `auto_explain.log_analyze` is enabled. This parameter is off by default. Only superusers can change this setting.

`auto_explain.log_wal (boolean)`

`auto_explain.log_wal` controls whether WAL usage statistics are printed when an execution plan is logged; it's equivalent to the `WAL` option of `EXPLAIN`. This parameter has no effect unless `auto_explain.log_analyze` is enabled. This parameter is off by default. Only superusers can change this setting.

`auto_explain.log_timing` (boolean)

`auto_explain.log_timing` controls whether per-node timing information is printed when an execution plan is logged; it's equivalent to the `TIMING` option of `EXPLAIN`. The overhead of repeatedly reading the system clock can slow down queries significantly on some systems, so it may be useful to set this parameter to off when only actual row counts, and not exact times, are needed. This parameter has no effect unless `auto_explain.log_analyze` is enabled. This parameter is on by default. Only superusers can change this setting.

`auto_explain.log_triggers` (boolean)

`auto_explain.log_triggers` causes trigger execution statistics to be included when an execution plan is logged. This parameter has no effect unless `auto_explain.log_analyze` is enabled. This parameter is off by default. Only superusers can change this setting.

`auto_explain.log_verbose` (boolean)

`auto_explain.log_verbose` controls whether verbose details are printed when an execution plan is logged; it's equivalent to the `VERBOSE` option of `EXPLAIN`. This parameter is off by default. Only superusers can change this setting.

`auto_explain.log_settings` (boolean)

`auto_explain.log_settings` controls whether information about modified configuration options is printed when an execution plan is logged. Only options affecting query planning with value different from the built-in default value are included in the output. This parameter is off by default. Only superusers can change this setting.

`auto_explain.log_format` (enum)

`auto_explain.log_format` selects the `EXPLAIN` output format to be used. The allowed values are `text`, `xml`, `json`, and `yaml`. The default is `text`. Only superusers can change this setting.

`auto_explain.log_level` (enum)

`auto_explain.log_level` selects the log level at which `auto_explain` will log the query plan. Valid values are `DEBUG5`, `DEBUG4`, `DEBUG3`, `DEBUG2`, `DEBUG1`, `INFO`, `NOTICE`, `WARNING`, and `LOG`. The default is `LOG`. Only superusers can change this setting.

`auto_explain.log_nested_statements` (boolean)

`auto_explain.log_nested_statements` causes nested statements (statements executed inside a function) to be considered for logging. When it is off, only top-level query plans are logged. This parameter is off by default. Only superusers can change this setting.

`auto_explain.sample_rate` (real)

`auto_explain.sample_rate` causes `auto_explain` to only explain a fraction of the statements in each session. The default is 1, meaning explain all the queries. In case of nested statements, either all will be explained or none. Only superusers can change this setting.

In ordinary usage, these parameters are set in `postgresql.conf`, although superusers can alter them on-the-fly within their own sessions. Typical usage might be:

```
# postgresql.conf
session_preload_libraries = 'auto_explain'

auto_explain.log_min_duration = '3s'
```

F.5.2. Example

```
postgres=# LOAD 'auto_explain';
postgres=# SET auto_explain.log_min_duration = 0;
```

```
postgres=# SET auto_explain.log_analyze = true;
postgres=# SELECT count(*)
           FROM pg_class, pg_index
           WHERE oid = indrelid AND indisunique;
```

This might produce log output such as:

```
LOG:  duration: 0.196 ms plan:
       Query Text: SELECT count(*)
                   FROM pg_class, pg_index
                   WHERE oid = indrelid AND indisunique;
       Aggregate  (cost=16.79..16.80 rows=1 width=0) (actual time=3.626..3.627 rows=1
loops=1)
         -> Hash Join  (cost=4.17..16.55 rows=92 width=0) (actual time=3.349..3.594 rows=92
loops=1)
           Hash Cond: (pg_class.oid = pg_index.indrelid)
             -> Seq Scan on pg_class  (cost=0.00..9.55 rows=255 width=4) (actual
time=0.016..0.140 rows=255 loops=1)
               -> Hash  (cost=3.02..3.02 rows=92 width=4) (actual time=3.238..3.238 rows=92
loops=1)
                 Buckets: 1024  Batches: 1  Memory Usage: 4kB
                 -> Seq Scan on pg_index  (cost=0.00..3.02 rows=92 width=4) (actual
time=0.008..3.187 rows=92 loops=1)
                   Filter: indisunique
       Planning Time: 0.548 ms
```

Note that Postgres Pro added a new field to the output to show planning time.

F.6. basebackup_to_shell — example "shell" pg_basebackup module

`basebackup_to_shell` adds a custom basebackup target called `shell`. This makes it possible to run `pg_basebackup --target=shell` or, depending on how this module is configured, `pg_basebackup --target=shell:DETAIL_STRING`, and cause a server command chosen by the server administrator to be executed for each tar archive generated by the backup process. The command will receive the contents of the archive via standard input.

This module is primarily intended as an example of how to create a new backup targets via an extension module, but in some scenarios it may be useful for its own sake. In order to function, this module must be loaded via [shared_preload_libraries](#) or [local_preload_libraries](#).

F.6.1. Configuration Parameters

`basebackup_to_shell.command (string)`

The command which the server should execute for each archive generated by the backup process. If `%f` occurs in the command string, it will be replaced by the name of the archive (e.g. `base.tar`). If `%d` occurs in the command string, it will be replaced by the target detail provided by the user. A target detail is required if `%d` is used in the command string, and prohibited otherwise. For security reasons, it may contain only alphanumeric characters. If `%%` occurs in the command string, it will be replaced by a single `%`. If `%` occurs in the command string followed by any other character or at the end of the string, an error occurs.

`basebackup_to_shell.required_role (string)`

The role required in order to make use of the `shell` backup target. If this is not set, any replication user may make use of the `shell` backup target.

F.6.2. Author

Robert Haas <rhaas@postgresql.org>

F.7. basic_archive — an example WAL archive module

`basic_archive` is an example of an archive module. This module copies completed WAL segment files to the specified directory. This may not be especially useful, but it can serve as a starting point for developing your own archive module. For more information about archive modules, see [Chapter 50](#).

In order to function, this module must be loaded via [archive_library](#), and [archive_mode](#) must be enabled.

F.7.1. Configuration Parameters

`basic_archive.archive_directory` (string)

The directory where the server should copy WAL segment files. This directory must already exist. The default is an empty string, which effectively halts WAL archiving, but if [archive_mode](#) is enabled, the server will accumulate WAL segment files in the expectation that a value will soon be provided.

These parameters must be set in `postgresql.conf`. Typical usage might be:

```
# postgresql.conf
archive_mode = 'on'
archive_library = 'basic_archive'
basic_archive.archive_directory = '/path/to/archive/directory'
```

F.7.2. Notes

Server crashes may leave temporary files with the prefix `archtemp` in the archive directory. It is recommended to delete such files before restarting the server after a crash. It is safe to remove such files while the server is running as long as they are unrelated to any archiving still in progress, but users should use extra caution when doing so.

Nathan Bossart

F.8. bloom — bloom filter index access method

`bloom` provides an index access method based on *Bloom filters*.

A Bloom filter is a space-efficient data structure that is used to test whether an element is a member of a set. In the case of an index access method, it allows fast exclusion of non-matching tuples via signatures whose size is determined at index creation.

A signature is a lossy representation of the indexed attribute(s), and as such is prone to reporting false positives; that is, it may be reported that an element is in the set, when it is not. So index search results must always be rechecked using the actual attribute values from the heap entry. Larger signatures reduce the odds of a false positive and thus reduce the number of useless heap visits, but of course also make the index larger and hence slower to scan.

This type of index is most useful when a table has many attributes and queries test arbitrary combinations of them. A traditional btree index is faster than a bloom index, but it can require many btree indexes to support all possible queries where one needs only a single bloom index. Note however that bloom indexes only support equality queries, whereas btree indexes can also perform inequality and range searches.

F.8.1. Parameters

A `bloom` index accepts the following parameters in its `WITH` clause:

`length`

Length of each signature (index entry) in bits. It is rounded up to the nearest multiple of 16. The default is 80 bits and the maximum is 4096.

`col1 – col32`

Number of bits generated for each index column. Each parameter's name refers to the number of the index column that it controls. The default is 2 bits and the maximum is 4095. Parameters for index columns not actually used are ignored.

F.8.2. Examples

This is an example of creating a bloom index:

```
CREATE INDEX bloomidx ON tbloom USING bloom (i1,i2,i3)
WITH (length=80, col1=2, col2=2, col3=4);
```

The index is created with a signature length of 80 bits, with attributes `i1` and `i2` mapped to 2 bits, and attribute `i3` mapped to 4 bits. We could have omitted the `length`, `col1`, and `col2` specifications since those have the default values.

Here is a more complete example of bloom index definition and usage, as well as a comparison with equivalent btree indexes. The bloom index is considerably smaller than the btree index, and can perform better.

```
=# CREATE TABLE tbloom AS
SELECT
  (random() * 1000000)::int as i1,
  (random() * 1000000)::int as i2,
  (random() * 1000000)::int as i3,
  (random() * 1000000)::int as i4,
  (random() * 1000000)::int as i5,
  (random() * 1000000)::int as i6
FROM
  generate_series(1,10000000);
SELECT 10000000
```

A sequential scan over this large table takes a long time:

```
=# EXPLAIN ANALYZE SELECT * FROM tbloom WHERE i2 = 898732 AND i5 = 123451;
```

```
-----  
Seq Scan on tbloom  (cost=0.00..213744.00 rows=250 width=24) (actual  
time=357.059..357.059 rows=0 loops=1)  
  Filter: ((i2 = 898732) AND (i5 = 123451))  
  Rows Removed by Filter: 10000000  
Planning Time: 0.346 ms  
Execution Time: 357.076 ms  
(5 rows)
```

Even with the btree index defined the result will still be a sequential scan:

```
=# CREATE INDEX btreeidx ON tbloom (i1, i2, i3, i4, i5, i6);  
CREATE INDEX  
=# SELECT pg_size_pretty(pg_relation_size('btreeidx'));  
pg_size_pretty  
-----  
386 MB  
(1 row)  
=# EXPLAIN ANALYZE SELECT * FROM tbloom WHERE i2 = 898732 AND i5 = 123451;  
QUERY PLAN  
-----  
-----
```

```
Seq Scan on tbloom  (cost=0.00..213744.00 rows=2 width=24) (actual  
time=351.016..351.017 rows=0 loops=1)  
  Filter: ((i2 = 898732) AND (i5 = 123451))  
  Rows Removed by Filter: 10000000  
Planning Time: 0.138 ms  
Execution Time: 351.035 ms  
(5 rows)
```

Having the bloom index defined on the table is better than btree in handling this type of search:

```
=# CREATE INDEX bloomidx ON tbloom USING bloom (i1, i2, i3, i4, i5, i6);  
CREATE INDEX  
=# SELECT pg_size_pretty(pg_relation_size('bloomidx'));  
pg_size_pretty  
-----  
153 MB  
(1 row)  
=# EXPLAIN ANALYZE SELECT * FROM tbloom WHERE i2 = 898732 AND i5 = 123451;  
QUERY PLAN  
-----  
-----  
Bitmap Heap Scan on tbloom  (cost=1792.00..1799.69 rows=2 width=24) (actual  
time=22.605..22.606 rows=0 loops=1)  
  Recheck Cond: ((i2 = 898732) AND (i5 = 123451))  
  Rows Removed by Index Recheck: 2300  
  Heap Blocks: exact=2256  
    -> Bitmap Index Scan on bloomidx  (cost=0.00..178436.00 rows=1 width=0) (actual  
time=20.005..20.005 rows=2300 loops=1)  
      Index Cond: ((i2 = 898732) AND (i5 = 123451))  
Planning Time: 0.099 ms  
Execution Time: 22.632 ms  
(8 rows)
```

Now, the main problem with the btree search is that btree is inefficient when the search conditions do not constrain the leading index column(s). A better strategy for btree is to create a separate index on each column. Then the planner will choose something like this:

```
=# CREATE INDEX btreeidx1 ON tbloom (i1);
CREATE INDEX
=# CREATE INDEX btreeidx2 ON tbloom (i2);
CREATE INDEX
=# CREATE INDEX btreeidx3 ON tbloom (i3);
CREATE INDEX
=# CREATE INDEX btreeidx4 ON tbloom (i4);
CREATE INDEX
=# CREATE INDEX btreeidx5 ON tbloom (i5);
CREATE INDEX
=# CREATE INDEX btreeidx6 ON tbloom (i6);
CREATE INDEX
=# EXPLAIN ANALYZE SELECT * FROM tbloom WHERE i2 = 898732 AND i5 = 123451;
                                QUERY PLAN
-----
Bitmap Heap Scan on tbloom  (cost=9.29..13.30 rows=1 width=24) (actual
time=0.032..0.033 rows=0 loops=1)
  Recheck Cond: ((i5 = 123451) AND (i2 = 898732))
    -> BitmapAnd  (cost=9.29..9.29 rows=1 width=0) (actual time=0.047..0.047 rows=0
loops=1)
      -> Bitmap Index Scan on btreeidx5  (cost=0.00..4.52 rows=11 width=0) (actual
time=0.026..0.026 rows=7 loops=1)
        Index Cond: (i5 = 123451)
      -> Bitmap Index Scan on btreeidx2  (cost=0.00..4.52 rows=11 width=0) (actual
time=0.007..0.007 rows=8 loops=1)
        Index Cond: (i2 = 898732)
Planning Time: 0.264 ms
Execution Time: 0.047 ms
(9 rows)
```

Although this query runs much faster than with either of the single indexes, we pay a penalty in index size. Each of the single-column btree indexes occupies 88.5 MB, so the total space needed is 531 MB, over three times the space used by the bloom index.

F.8.3. Operator Class Interface

An operator class for bloom indexes requires only a hash function for the indexed data type and an equality operator for searching. This example shows the operator class definition for the `text` data type:

```
CREATE OPERATOR CLASS text_ops
DEFAULT FOR TYPE text USING bloom AS
    OPERATOR      1      =(text, text),
    FUNCTION      1      hashtext(text);
```

F.8.4. Limitations

- Only operator classes for `int4` and `text` are included with the module.
- Only the `=` operator is supported for search. But it is possible to add support for arrays with union and intersection operations in the future.
- `bloom` access method doesn't support `UNIQUE` indexes.
- `bloom` access method doesn't support searching for `NULL` values.

F.9. btree_gin — GIN operator classes with B-tree behavior

`btree_gin` provides GIN operator classes that implement B-tree equivalent behavior for the data types `int2`, `int4`, `int8`, `float4`, `float8`, `timestamp with time zone`, `timestamp without time zone`, `time with time zone`, `time without time zone`, `date`, `interval`, `oid`, `money`, `"char"`, `varchar`, `text`, `bytea`, `bit`, `varbit`, `macaddr`, `macaddr8`, `inet`, `cidr`, `uuid`, `name`, `bool`, `bpchar`, and all enum types.

In general, these operator classes will not outperform the equivalent standard B-tree index methods, and they lack one major feature of the standard B-tree code: the ability to enforce uniqueness. However, they are useful for GIN testing and as a base for developing other GIN operator classes. Also, for queries that test both a GIN-indexable column and a B-tree-indexable column, it might be more efficient to create a multicolumn GIN index that uses one of these operator classes than to create two separate indexes that would have to be combined via bitmap ANDing.

This module is considered “trusted”, that is, it can be installed by non-superusers who have `CREATE` privilege on the current database.

F.9.1. Example Usage

```
CREATE TABLE test (a int4);
-- create index
CREATE INDEX testidx ON test USING GIN (a);
-- query
SELECT * FROM test WHERE a < 10;
```

F.9.2. Authors

Teodor Sigaev (<teodor@stack.net>) and Oleg Bartunov (<oleg@sai.msu.su>). See <http://www.sai.msu.su/~megeera/oddmuse/index.cgi/Gin> for additional information.

F.10. btree_gist — GiST operator classes with B-tree behavior

`btree_gist` provides GiST index operator classes that implement B-tree equivalent behavior for the data types `int2`, `int4`, `int8`, `float4`, `float8`, `numeric`, `timestamp with time zone`, `timestamp without time zone`, `time with time zone`, `time without time zone`, `date`, `interval`, `oid`, `money`, `char`, `varchar`, `text`, `bytea`, `bit`, `varbit`, `macaddr`, `macaddr8`, `inet`, `cidr`, `uuid`, `bool` and all enum types.

In general, these operator classes will not outperform the equivalent standard B-tree index methods, and they lack one major feature of the standard B-tree code: the ability to enforce uniqueness. However, they provide some other features that are not available with a B-tree index, as described below. Also, these operator classes are useful when a multicolumn GiST index is needed, wherein some of the columns are of data types that are only indexable with GiST but other columns are just simple data types. Lastly, these operator classes are useful for GiST testing and as a base for developing other GiST operator classes.

In addition to the typical B-tree search operators, `btree_gist` also provides index support for `<>` (“not equals”). This may be useful in combination with an [exclusion constraint](#), as described below.

Also, for data types for which there is a natural distance metric, `btree_gist` defines a distance operator `<->`, and provides GiST index support for nearest-neighbor searches using this operator. Distance operators are provided for `int2`, `int4`, `int8`, `float4`, `float8`, `timestamp with time zone`, `timestamp without time zone`, `time without time zone`, `date`, `interval`, `oid`, and `money`.

This module is considered “trusted”, that is, it can be installed by non-superusers who have `CREATE` privilege on the current database.

F.10.1. Example Usage

Simple example using `btree_gist` instead of `btree`:

```
CREATE TABLE test (a int4);
-- create index
CREATE INDEX testidx ON test USING GIST (a);
-- query
SELECT * FROM test WHERE a < 10;
-- nearest-neighbor search: find the ten entries closest to "42"
SELECT *, a <-> 42 AS dist FROM test ORDER BY a <-> 42 LIMIT 10;
```

Use an [exclusion constraint](#) to enforce the rule that a cage at a zoo can contain only one kind of animal:

```
=> CREATE TABLE zoo (
    cage    INTEGER,
    animal  TEXT,
    EXCLUDE USING GIST (cage WITH =, animal WITH <>)
);

=> INSERT INTO zoo VALUES(123, 'zebra');
INSERT 0 1
=> INSERT INTO zoo VALUES(123, 'zebra');
INSERT 0 1
=> INSERT INTO zoo VALUES(123, 'lion');
ERROR:  conflicting key value violates exclusion constraint "zoo_cage_animal_excl"
DETAIL:  Key (cage, animal)=(123, lion) conflicts with existing key (cage,
        animal)=(123, zebra).
=> INSERT INTO zoo VALUES(124, 'lion');
INSERT 0 1
```

F.10.2. Authors

Teodor Sigaev (<teodor@stack.net>), Oleg Bartunov (<oleg@sai.msu.su>), Janko Richter (<janko-richter@yahoo.de>), and Paul Jungwirth (<pj@illuminatedcomputing.com>). See <http://www.sai.msu.su/~megera/postgres/gist/> for additional information.

F.11. citext — a case-insensitive character string type

The `citext` module provides a case-insensitive character string type, `citext`. Essentially, it internally calls `lower` when comparing values. Otherwise, it behaves almost exactly like `text`.

Tip

Consider using *nondeterministic collations* (see [Section 22.2.2.4](#)) instead of this module. They can be used for case-insensitive comparisons, accent-insensitive comparisons, and other combinations, and they handle more Unicode special cases correctly.

This module is considered “trusted”, that is, it can be installed by non-superusers who have `CREATE` privilege on the current database.

F.11.1. Rationale

The standard approach to doing case-insensitive matches in Postgres Pro has been to use the `lower` function when comparing values, for example

```
SELECT * FROM tab WHERE lower(col) = LOWER(?);
```

This works reasonably well, but has a number of drawbacks:

- It makes your SQL statements verbose, and you always have to remember to use `lower` on both the column and the query value.
- It won't use an index, unless you create a functional index using `lower`.
- If you declare a column as `UNIQUE` or `PRIMARY KEY`, the implicitly generated index is case-sensitive. So it's useless for case-insensitive searches, and it won't enforce uniqueness case-insensitively.

The `citext` data type allows you to eliminate calls to `lower` in SQL queries, and allows a primary key to be case-insensitive. `citext` is locale-aware, just like `text`, which means that the matching of upper case and lower case characters is dependent on the rules of the database's `LC_CTYPE` setting. Again, this behavior is identical to the use of `lower` in queries. But because it's done transparently by the data type, you don't have to remember to do anything special in your queries.

F.11.2. How to Use It

Here's a simple example of usage:

```
CREATE TABLE users (  
    nick CITEXT PRIMARY KEY,  
    pass TEXT    NOT NULL  
);  
  
INSERT INTO users VALUES ( 'larry',  sha256(random()::text::bytea) );  
INSERT INTO users VALUES ( 'Tom',    sha256(random()::text::bytea) );  
INSERT INTO users VALUES ( 'Damian',  sha256(random()::text::bytea) );  
INSERT INTO users VALUES ( 'NEAL',   sha256(random()::text::bytea) );  
INSERT INTO users VALUES ( 'Bjørn',   sha256(random()::text::bytea) );  
  
SELECT * FROM users WHERE nick = 'Larry';
```

The `SELECT` statement will return one tuple, even though the `nick` column was set to `larry` and the query was for `Larry`.

F.11.3. String Comparison Behavior

`citext` performs comparisons by converting each string to lower case (as though `lower` were called) and then comparing the results normally. Thus, for example, two strings are considered equal if `lower` would produce identical results for them.

In order to emulate a case-insensitive collation as closely as possible, there are `citext`-specific versions of a number of string-processing operators and functions. So, for example, the regular expression operators `~` and `~*` exhibit the same behavior when applied to `citext`: they both match case-insensitively. The same is true for `!~` and `!~*`, as well as for the `LIKE` operators `~~` and `~~*`, and `!~~` and `!~~*`. If you'd like to match case-sensitively, you can cast the operator's arguments to `text`.

Similarly, all of the following functions perform matching case-insensitively if their arguments are `citext`:

- `regexp_match()`
- `regexp_matches()`
- `regexp_replace()`
- `regexp_split_to_array()`
- `regexp_split_to_table()`
- `replace()`
- `split_part()`
- `strpos()`
- `translate()`

For the `regexp` functions, if you want to match case-sensitively, you can specify the “c” flag to force a case-sensitive match. Otherwise, you must cast to `text` before using one of these functions if you want case-sensitive behavior.

F.11.4. Limitations

- `citext`'s case-folding behavior depends on the `LC_CTYPE` setting of your database. How it compares values is therefore determined when the database is created. It is not truly case-insensitive in the terms defined by the Unicode standard. Effectively, what this means is that, as long as you're happy with your collation, you should be happy with `citext`'s comparisons. But if you have data in different languages stored in your database, users of one language may find their query results are not as expected if the collation is for another language.
- As of PostgreSQL 9.1, you can attach a `COLLATE` specification to `citext` columns or data values. Currently, `citext` operators will honor a non-default `COLLATE` specification while comparing case-folded strings, but the initial folding to lower case is always done according to the database's `LC_CTYPE` setting (that is, as though `COLLATE "default"` were given). This may be changed in a future release so that both steps follow the input `COLLATE` specification.
- `citext` is not as efficient as `text` because the operator functions and the B-tree comparison functions must make copies of the data and convert it to lower case for comparisons. Also, only `text` can support B-Tree deduplication. However, `citext` is slightly more efficient than using `lower` to get case-insensitive matching.
- `citext` doesn't help much if you need data to compare case-sensitively in some contexts and case-insensitively in other contexts. The standard answer is to use the `text` type and manually use the `lower` function when you need to compare case-insensitively; this works all right if case-insensitive comparison is needed only infrequently. If you need case-insensitive behavior most of the time and case-sensitive infrequently, consider storing the data as `citext` and explicitly casting the column to `text` when you want case-sensitive comparison. In either situation, you will need two indexes if you want both types of searches to be fast.
- The schema containing the `citext` operators must be in the current `search_path` (typically `public`); if it is not, the normal case-sensitive `text` operators will be invoked instead.
- The approach of lower-casing strings for comparison does not handle some Unicode special cases correctly, for example when one upper-case letter has two lower-case letter equivalents. Unicode

distinguishes between *case mapping* and *case folding* for this reason. Use nondeterministic collations instead of `citext` to handle that correctly.

F.11.5. Author

David E. Wheeler <david@kineticode.com>

Inspired by the original `citext` module by Donald Fraser.

F.12. cube — a multi-dimensional cube data type

This module implements a data type `cube` for representing multidimensional cubes.

This module is considered “trusted”, that is, it can be installed by non-superusers who have `CREATE` privilege on the current database.

F.12.1. Syntax

[Table F.6](#) shows the valid external representations for the `cube` type. x , y , etc. denote floating-point numbers.

Table F.6. Cube External Representations

External Syntax	Meaning
x	A one-dimensional point (or, zero-length one-dimensional interval)
(x)	Same as above
$x1, x2, \dots, xn$	A point in n -dimensional space, represented internally as a zero-volume cube
$(x1, x2, \dots, xn)$	Same as above
$(x), (y)$	A one-dimensional interval starting at x and ending at y or vice versa; the order does not matter
$[(x), (y)]$	Same as above
$(x1, \dots, xn), (y1, \dots, yn)$	An n -dimensional cube represented by a pair of its diagonally opposite corners
$[(x1, \dots, xn), (y1, \dots, yn)]$	Same as above

It does not matter which order the opposite corners of a cube are entered in. The `cube` functions automatically swap values if needed to create a uniform “lower left — upper right” internal representation. When the corners coincide, `cube` stores only one corner along with an “is point” flag to avoid wasting space.

White space is ignored on input, so $[(x), (y)]$ is the same as $[(x), (y)]$.

F.12.2. Precision

Values are stored internally as 64-bit floating point numbers. This means that numbers with more than about 16 significant digits will be truncated.

F.12.3. Usage

[Table F.7](#) shows the specialized operators provided for type `cube`.

Table F.7. Cube Operators

Operator	Description
<code>cube && cube</code>	<code>→ boolean</code> Do the cubes overlap?
<code>cube @> cube</code>	<code>→ boolean</code> Does the first cube contain the second?
<code>cube <@ cube</code>	<code>→ boolean</code> Is the first cube contained in the second?
<code>cube -> integer</code>	<code>→ float8</code> Extracts the n -th coordinate of the cube (counting from 1).

Operator	Description
<code>cube ~> integer → float8</code>	Extracts the n -th coordinate of the cube, counting in the following way: $n = 2 * k - 1$ means lower bound of k -th dimension, $n = 2 * k$ means upper bound of k -th dimension. Negative n denotes the inverse value of the corresponding positive coordinate. This operator is designed for KNN-GiST support.
<code>cube <-> cube → float8</code>	Computes the Euclidean distance between the two cubes.
<code>cube <#> cube → float8</code>	Computes the taxicab (L-1 metric) distance between the two cubes.
<code>cube <=> cube → float8</code>	Computes the Chebyshev (L-inf metric) distance between the two cubes.

In addition to the above operators, the usual comparison operators shown in [Table 9.1](#) are available for type `cube`. These operators first compare the first coordinates, and if those are equal, compare the second coordinates, etc. They exist mainly to support the b-tree index operator class for `cube`, which can be useful for example if you would like a UNIQUE constraint on a `cube` column. Otherwise, this ordering is not of much practical use.

The `cube` module also provides a GiST index operator class for `cube` values. A `cube` GiST index can be used to search for values using the `=`, `&&`, `@>`, and `<@` operators in WHERE clauses.

In addition, a `cube` GiST index can be used to find nearest neighbors using the metric operators `<->`, `<#>`, and `<=>` in ORDER BY clauses. For example, the nearest neighbor of the 3-D point (0.5, 0.5, 0.5) could be found efficiently with:

```
SELECT c FROM test ORDER BY c <-> cube(array[0.5,0.5,0.5]) LIMIT 1;
```

The `~>` operator can also be used in this way to efficiently retrieve the first few values sorted by a selected coordinate. For example, to get the first few cubes ordered by the first coordinate (lower left corner) ascending one could use the following query:

```
SELECT c FROM test ORDER BY c ~> 1 LIMIT 5;
```

And to get 2-D cubes ordered by the first coordinate of the upper right corner descending:

```
SELECT c FROM test ORDER BY c ~> 3 DESC LIMIT 5;
```

[Table F.8](#) shows the available functions.

Table F.8. Cube Functions

Function	Description	Example(s)
<code>cube (float8) → cube</code>	Makes a one dimensional cube with both coordinates the same.	<code>cube(1) → (1)</code>
<code>cube (float8, float8) → cube</code>	Makes a one dimensional cube.	<code>cube(1, 2) → (1), (2)</code>
<code>cube (float8[]) → cube</code>	Makes a zero-volume cube using the coordinates defined by the array.	<code>cube(ARRAY[1,2,3]) → (1, 2, 3)</code>
<code>cube (float8[], float8[]) → cube</code>		

Function	Description	Example(s)
	Makes a cube with upper right and lower left coordinates as defined by the two arrays, which must be of the same length.	<code>cube (ARRAY[1,2], ARRAY[3,4])</code> → (1, 2), (3, 4)
<code>cube (cube, float8)</code> → cube	Makes a new cube by adding a dimension on to an existing cube, with the same values for both endpoints of the new coordinate. This is useful for building cubes piece by piece from calculated values.	<code>cube ('(1,2), (3,4) '::cube, 5)</code> → (1, 2, 5), (3, 4, 5)
<code>cube (cube, float8, float8)</code> → cube	Makes a new cube by adding a dimension on to an existing cube. This is useful for building cubes piece by piece from calculated values.	<code>cube ('(1,2), (3,4) '::cube, 5, 6)</code> → (1, 2, 5), (3, 4, 6)
<code>cube_dim (cube)</code> → integer	Returns the number of dimensions of the cube.	<code>cube_dim ('(1,2), (3,4) ')</code> → 2
<code>cube_ll_coord (cube, integer)</code> → float8	Returns the <i>n</i> -th coordinate value for the lower left corner of the cube.	<code>cube_ll_coord ('(1,2), (3,4) ', 2)</code> → 2
<code>cube_ur_coord (cube, integer)</code> → float8	Returns the <i>n</i> -th coordinate value for the upper right corner of the cube.	<code>cube_ur_coord ('(1,2), (3,4) ', 2)</code> → 4
<code>cube_is_point (cube)</code> → boolean	Returns true if the cube is a point, that is, the two defining corners are the same.	<code>cube_is_point (cube(1,1))</code> → t
<code>cube_distance (cube, cube)</code> → float8	Returns the distance between two cubes. If both cubes are points, this is the normal distance function.	<code>cube_distance ('(1,2) ', '(3,4) ')</code> → 2.8284271247461903
<code>cube_subset (cube, integer[])</code> → cube	Makes a new cube from an existing cube, using a list of dimension indexes from an array. Can be used to extract the endpoints of a single dimension, or to drop dimensions, or to reorder them as desired.	<code>cube_subset (cube ('(1,3,5), (6,7,8) '), ARRAY[2])</code> → (3), (7) <code>cube_subset (cube ('(1,3,5), (6,7,8) '), ARRAY[3,2,1,1])</code> → (5, 3, 1, 1), (8, 7, 6, 6)
<code>cube_union (cube, cube)</code> → cube	Produces the union of two cubes.	<code>cube_union ('(1,2) ', '(3,4) ')</code> → (1, 2), (3, 4)
<code>cube_inter (cube, cube)</code> → cube	Produces the intersection of two cubes.	<code>cube_inter ('(1,2) ', '(3,4) ')</code> → (3, 4), (1, 2)
<code>cube_enlarge (c cube, r double, n integer)</code> → cube	Increases the size of the cube by the specified radius <i>r</i> in at least <i>n</i> dimensions. If the radius is negative the cube is shrunk instead. All defined dimensions are changed by the radius <i>r</i> .	

Function	Description	Example(s)
	Lower-left coordinates are decreased by r and upper-right coordinates are increased by r . If a lower-left coordinate is increased to more than the corresponding upper-right coordinate (this can only happen when $r < 0$) then both coordinates are set to their average. If n is greater than the number of defined dimensions and the cube is being enlarged ($r > 0$), then extra dimensions are added to make n altogether; 0 is used as the initial value for the extra coordinates. This function is useful for creating bounding boxes around a point for searching for nearby points.	<code>cube_enlarge(' (1,2), (3,4) ', 0.5, 3)</code> $\rightarrow$ <code>(0.5, 1.5, -0.5), (3.5, 4.5, 0.5)</code>

F.12.4. Defaults

This union:

```
select cube_union(' (0,5,2), (2,3,1) ', '0');
cube_union
-----
(0, 0, 0), (2, 5, 2)
(1 row)
```

does not contradict common sense, neither does the intersection:

```
select cube_inter(' (0,-1), (1,1) ', ' (-2), (2) ');
cube_inter
-----
(0, 0), (1, 0)
(1 row)
```

In all binary operations on differently-dimensioned cubes, the lower-dimensional one is assumed to be a Cartesian projection, i. e., having zeroes in place of coordinates omitted in the string representation. The above examples are equivalent to:

```
cube_union(' (0,5,2), (2,3,1) ', ' (0,0,0), (0,0,0) ');
cube_inter(' (0,-1), (1,1) ', ' (-2,0), (2,0) ');
```

The following containment predicate uses the point syntax, while in fact the second argument is internally represented by a box. This syntax makes it unnecessary to define a separate point type and functions for (box,point) predicates.

```
select cube_contains(' (0,0), (1,1) ', '0.5,0.5');
cube_contains
-----
t
(1 row)
```

F.12.5. Notes

For examples of usage, see the regression test `sql/cube.sql`.

To make it harder for people to break things, there is a limit of 100 on the number of dimensions of cubes. This is set in `cubedata.h` if you need something bigger.

F.12.6. Credits

Original author: Gene Selkov, Jr. <selkovjr@mcs.anl.gov>, Mathematics and Computer Science Division, Argonne National Laboratory.

Additional Supplied Modules
and Extensions Shipped in
postgrespro-std-16-contrib

My thanks are primarily to Prof. Joe Hellerstein (<https://dsf.berkeley.edu/jmh/>) for elucidating the gist of the GiST (<http://gist.cs.berkeley.edu/>), and to his former student Andy Dong for his example written for Illustra. I am also grateful to all Postgres developers, present and past, for enabling myself to create my own world and live undisturbed in it. And I would like to acknowledge my gratitude to Argonne Lab and to the U.S. Department of Energy for the years of faithful support of my database research.

Minor updates to this package were made by Bruno Wolff III <bruno@wolff.to> in August/September of 2002. These include changing the precision from single precision to double precision and adding some new functions.

Additional updates were made by Joshua Reich <josh@root.net> in July 2006. These include `cube(float8[], float8[])` and cleaning up the code to use the V1 call protocol instead of the deprecated V0 protocol.

F.13. daterange_inclusive — upper bound-inclusive daterange

`daterange_inclusive` is an extension to the built-in `daterange` range type. By default, `daterange` excludes the upper bound of the range — `[]`, whereas `daterange_inclusive` does not — `[]`. Other than the covered range bound, there are no other differences between `daterange` and `daterange_inclusive`.

This module is considered “trusted”, that is, it can be installed by non-superusers who have `CREATE` privilege on the current database.

F.13.1. Rationale

At times, it is more convenient to output date ranges with inclusive upper bounds. For example, it may apply to employees' absences. If an employee is absent from January 1, 2025, to January 10, 2025, using the `daterange` range type will prevent the database from outputting this date range in its entirety. In such cases, you would need to manually subtract one day from the output. The `daterange_inclusive` extension addresses this issue.

F.13.2. Example Usage

```
CREATE EXTENSION daterange_inclusive;
SELECT daterange('2024-01-01,2024-06-01');
       daterange
-----
[2024-01-01,2024-06-02)

SELECT daterange_inclusive('2024-01-01,2024-06-01');
       daterange_inclusive
-----
[2024-01-01,2024-06-01]
```

F.14. `dbcopies_decoding` — 1C module for updating database copies

`dbcopies_decoding` is a 1C module for updating database copies. It is implemented as a logical replication plug-in and provided in `postgrespro-std-16-contrib`. For the module to work properly, `wal_level` must be set to `logical`. For more information about this module contact 1C support.

F.15. dblink — connect to other Postgres Pro databases

`dblink` is a module that supports connections to other Postgres Pro databases from within a database session.

See also [postgres_fdw](#), which provides roughly the same functionality using a more modern and standards-compliant infrastructure.

dblink_connect

`dblink_connect` — opens a persistent connection to a remote database

Synopsis

```
dblink_connect(text connstr) returns text
dblink_connect(text connname, text connstr) returns text
```

Description

`dblink_connect()` establishes a connection to a remote Postgres Pro database. The server and database to be contacted are identified through a standard libpq connection string. Optionally, a name can be assigned to the connection. Multiple named connections can be open at once, but only one unnamed connection is permitted at a time. The connection will persist until closed or until the database session is ended.

The connection string may also be the name of an existing foreign server. It is recommended to use the foreign-data wrapper `dblink_fdw` when defining the foreign server. See the example below, as well as [CREATE SERVER](#) and [CREATE USER MAPPING](#).

Arguments

connname

The name to use for this connection; if omitted, an unnamed connection is opened, replacing any existing unnamed connection.

connstr

libpq-style connection info string, for example `hostaddr=127.0.0.1 port=5432 dbname=mydb user=postgres password=mypasswd options=-csearch_path=`. For details see [Section 33.1.1](#). Alternatively, the name of a foreign server.

Return Value

Returns status, which is always OK (since any error causes the function to throw an error instead of returning).

Notes

If untrusted users have access to a database that has not adopted a [secure schema usage pattern](#), begin each session by removing publicly-writable schemas from `search_path`. One could, for example, add `options=-csearch_path=` to *connstr*. This consideration is not specific to `dblink`; it applies to every interface for executing arbitrary SQL commands.

Only superusers may use `dblink_connect` to create non-password-authenticated and non-GSSAPI-authenticated connections. If non-superusers need this capability, use `dblink_connect_u` instead.

It is unwise to choose connection names that contain equal signs, as this opens a risk of confusion with connection info strings in other `dblink` functions.

Examples

```
SELECT dblink_connect('dbname=postgres options=-csearch_path=');
 dblink_connect
-----
 OK
(1 row)

SELECT dblink_connect('myconn', 'dbname=postgres options=-csearch_path=');
```

```

dblink_connect_u

`dblink_connect_u` — opens a persistent connection to a remote database, insecurely

Synopsis

```
dblink_connect_u(text connstr) returns text  
dblink_connect_u(text connname, text connstr) returns text
```

Description

`dblink_connect_u()` is identical to `dblink_connect()`, except that it will allow non-superusers to connect using any authentication method.

If the remote server selects an authentication method that does not involve a password, then impersonation and subsequent escalation of privileges can occur, because the session will appear to have originated from the user as which the local Postgres Pro server runs. Also, even if the remote server does demand a password, it is possible for the password to be supplied from the server environment, such as a `~/.pgpass` file belonging to the server's user. This opens not only a risk of impersonation, but the possibility of exposing a password to an untrustworthy remote server. Therefore, `dblink_connect_u()` is initially installed with all privileges revoked from `PUBLIC`, making it un-callable except by superusers. In some situations it may be appropriate to grant `EXECUTE` permission for `dblink_connect_u()` to specific users who are considered trustworthy, but this should be done with care. It is also recommended that any `~/.pgpass` file belonging to the server's user *not* contain any records specifying a wildcard host name.

For further details see `dblink_connect()`.

dblink_disconnect

`dblink_disconnect` — closes a persistent connection to a remote database

Synopsis

```
dblink_disconnect() returns text  
dblink_disconnect(text connname) returns text
```

Description

`dblink_disconnect()` closes a connection previously opened by `dblink_connect()`. The form with no arguments closes an unnamed connection.

Arguments

connname

The name of a named connection to be closed.

Return Value

Returns status, which is always `OK` (since any error causes the function to throw an error instead of returning).

Examples

```
SELECT dblink_disconnect();  
dblink_disconnect  
-----  
OK  
(1 row)  
  
SELECT dblink_disconnect('myconn');  
dblink_disconnect  
-----  
OK  
(1 row)
```

dblink

`dblink` — executes a query in a remote database

Synopsis

```
dblink(text connname, text sql [, bool fail_on_error]) returns setof record
dblink(text connstr, text sql [, bool fail_on_error]) returns setof record
dblink(text sql [, bool fail_on_error]) returns setof record
```

Description

`dblink` executes a query (usually a `SELECT`, but it can be any SQL statement that returns rows) in a remote database.

When two `text` arguments are given, the first one is first looked up as a persistent connection's name; if found, the command is executed on that connection. If not found, the first argument is treated as a connection info string as for `dblink_connect`, and the indicated connection is made just for the duration of this command.

Arguments

connname

Name of the connection to use; omit this parameter to use the unnamed connection.

connstr

A connection info string, as previously described for `dblink_connect`.

sql

The SQL query that you wish to execute in the remote database, for example `select * from foo`.

fail_on_error

If true (the default when omitted) then an error thrown on the remote side of the connection causes an error to also be thrown locally. If false, the remote error is locally reported as a `NOTICE`, and the function returns no rows.

Return Value

The function returns the row(s) produced by the query. Since `dblink` can be used with any query, it is declared to return `record`, rather than specifying any particular set of columns. This means that you must specify the expected set of columns in the calling query — otherwise Postgres Pro would not know what to expect. Here is an example:

```
SELECT *
FROM dblink('dbname=mydb options=-csearch_path=',
            'select pronomame, prosrc from pg_proc')
AS t1(pronomame name, prosrc text)
WHERE pronomame LIKE 'bytea%';
```

The “alias” part of the `FROM` clause must specify the column names and types that the function will return. (Specifying column names in an alias is actually standard SQL syntax, but specifying column types is a Postgres Pro extension.) This allows the system to understand what `*` should expand to, and what `pronomame` in the `WHERE` clause refers to, in advance of trying to execute the function. At run time, an error will be thrown if the actual query result from the remote database does not have the same number of columns shown in the `FROM` clause. The column names need not match, however, and `dblink` does not insist on exact type matches either. It will succeed so long as the returned data strings are valid input for the column type declared in the `FROM` clause.

Notes

A convenient way to use `dblink` with predetermined queries is to create a view. This allows the column type information to be buried in the view, instead of having to spell it out in every query. For example,

```
CREATE VIEW myremote_pg_proc AS
  SELECT *
    FROM dblink('dbname=postgres options=-csearch_path=',
                'select proname, prosrc from pg_proc')
    AS t1(proname name, prosrc text);

SELECT * FROM myremote_pg_proc WHERE proname LIKE 'bytea%';
```

Examples

```
SELECT * FROM dblink('dbname=postgres options=-csearch_path=',
                    'select proname, prosrc from pg_proc')
  AS t1(proname name, prosrc text) WHERE proname LIKE 'bytea%';
 proname | prosrc
-----+-----
 byteacat | byteacat

dblink_exec

`dblink_exec` — executes a command in a remote database

Synopsis

```
dblink_exec(text connname, text sql [, bool fail_on_error]) returns text
dblink_exec(text connstr, text sql [, bool fail_on_error]) returns text
dblink_exec(text sql [, bool fail_on_error]) returns text
```

Description

`dblink_exec` executes a command (that is, any SQL statement that doesn't return rows) in a remote database.

When two `text` arguments are given, the first one is first looked up as a persistent connection's name; if found, the command is executed on that connection. If not found, the first argument is treated as a connection info string as for `dblink_connect`, and the indicated connection is made just for the duration of this command.

Arguments

connname

Name of the connection to use; omit this parameter to use the unnamed connection.

connstr

A connection info string, as previously described for `dblink_connect`.

sql

The SQL command that you wish to execute in the remote database, for example `insert into foo values (0, 'a', '{"a0","b0","c0"}')`.

fail_on_error

If true (the default when omitted) then an error thrown on the remote side of the connection causes an error to also be thrown locally. If false, the remote error is locally reported as a NOTICE, and the function's return value is set to `ERROR`.

Return Value

Returns status, either the command's status string or `ERROR`.

Examples

```
SELECT dblink_connect('dbname=dblink_test_standby');
 dblink_connect
-----
 OK
(1 row)

SELECT dblink_exec('insert into foo values(21, ''z'', ''{"a0","b0","c0"}'');');
 dblink_exec
-----
 INSERT 943366 1
(1 row)

SELECT dblink_connect('myconn', 'dbname=regression');
 dblink_connect
```

```
-----
OK
(1 row)

SELECT dblink_exec('myconn', 'insert into foo values(21, ''z'',
''{"a0","b0","c0"}'');');
      dblink_exec
-----
INSERT 6432584 1
(1 row)

SELECT dblink_exec('myconn', 'insert into pg_class values (''foo''),false);
NOTICE:  sql error
DETAIL:  ERROR:  null value in column "relnamespace" violates not-null constraint

      dblink_exec
-----
ERROR
(1 row)
```

dblink_open

`dblink_open` — opens a cursor in a remote database

Synopsis

```
dblink_open(text cursorname, text sql [, bool fail_on_error]) returns text
dblink_open(text connname, text cursorname, text sql [, bool fail_on_error]) returns
text
```

Description

`dblink_open()` opens a cursor in a remote database. The cursor can subsequently be manipulated with `dblink_fetch()` and `dblink_close()`.

Arguments

connname

Name of the connection to use; omit this parameter to use the unnamed connection.

cursorname

The name to assign to this cursor.

sql

The `SELECT` statement that you wish to execute in the remote database, for example `select * from pg_class`.

fail_on_error

If true (the default when omitted) then an error thrown on the remote side of the connection causes an error to also be thrown locally. If false, the remote error is locally reported as a NOTICE, and the function's return value is set to `ERROR`.

Return Value

Returns status, either `OK` or `ERROR`.

Notes

Since a cursor can only persist within a transaction, `dblink_open` starts an explicit transaction block (`BEGIN`) on the remote side, if the remote side was not already within a transaction. This transaction will be closed again when the matching `dblink_close` is executed. Note that if you use `dblink_exec` to change data between `dblink_open` and `dblink_close`, and then an error occurs or you use `dblink_disconnect` before `dblink_close`, your change *will be lost* because the transaction will be aborted.

Examples

```
SELECT dblink_connect('dbname=postgres options=-csearch_path=');
dblink_connect
```

```
-----
OK
(1 row)
```

```
SELECT dblink_open('foo', 'select proname, prosrc from pg_proc');
dblink_open
```

```
-----
OK
(1 row)
```

dblink_fetch

`dblink_fetch` — returns rows from an open cursor in a remote database

Synopsis

```
dblink_fetch(text cursorname, int howmany [, bool fail_on_error]) returns setof record
dblink_fetch(text connname, text cursorname, int howmany [, bool fail_on_error])
returns setof record
```

Description

`dblink_fetch` fetches rows from a cursor previously established by `dblink_open`.

Arguments

connname

Name of the connection to use; omit this parameter to use the unnamed connection.

cursorname

The name of the cursor to fetch from.

howmany

The maximum number of rows to retrieve. The next *howmany* rows are fetched, starting at the current cursor position, moving forward. Once the cursor has reached its end, no more rows are produced.

fail_on_error

If true (the default when omitted) then an error thrown on the remote side of the connection causes an error to also be thrown locally. If false, the remote error is locally reported as a NOTICE, and the function returns no rows.

Return Value

The function returns the row(s) fetched from the cursor. To use this function, you will need to specify the expected set of columns, as previously discussed for `dblink`.

Notes

On a mismatch between the number of return columns specified in the `FROM` clause, and the actual number of columns returned by the remote cursor, an error will be thrown. In this event, the remote cursor is still advanced by as many rows as it would have been if the error had not occurred. The same is true for any other error occurring in the local query after the remote `FETCH` has been done.

Examples

```
SELECT dblink_connect('dbname=postgres options=-csearch_path=');
dblink_connect
```

```
-----
OK
(1 row)

-----+-----
(0 rows)
```

dblink_close

`dblink_close` — closes a cursor in a remote database

Synopsis

```
dblink_close(text cursorname [, bool fail_on_error]) returns text
dblink_close(text connname, text cursorname [, bool fail_on_error]) returns text
```

Description

`dblink_close` closes a cursor previously opened with `dblink_open`.

Arguments

connname

Name of the connection to use; omit this parameter to use the unnamed connection.

cursorname

The name of the cursor to close.

fail_on_error

If true (the default when omitted) then an error thrown on the remote side of the connection causes an error to also be thrown locally. If false, the remote error is locally reported as a NOTICE, and the function's return value is set to `ERROR`.

Return Value

Returns status, either `OK` or `ERROR`.

Notes

If `dblink_open` started an explicit transaction block, and this is the last remaining open cursor in this connection, `dblink_close` will issue the matching `COMMIT`.

Examples

```
SELECT dblink_connect('dbname=postgres options=-csearch_path=');
 dblink_connect
-----
 OK
(1 row)

SELECT dblink_open('foo', 'select proname, prosrc from pg_proc');
 dblink_open
-----
 OK
(1 row)

SELECT dblink_close('foo');
 dblink_close
-----
 OK
(1 row)
```

dblink_get_connections

`dblink_get_connections` — returns the names of all open named dblink connections

Synopsis

```
dblink_get_connections() returns text[]
```

Description

`dblink_get_connections` returns an array of the names of all open named dblink connections.

Return Value

Returns a text array of connection names, or NULL if none.

Examples

```
SELECT dblink_get_connections();
```

dblink_error_message

`dblink_error_message` — gets last error message on the named connection

Synopsis

```
dblink_error_message(text connname) returns text
```

Description

`dblink_error_message` fetches the most recent remote error message for a given connection.

Arguments

connname

Name of the connection to use.

Return Value

Returns last error message, or OK if there has been no error in this connection.

Notes

When asynchronous queries are initiated by `dblink_send_query`, the error message associated with the connection might not get updated until the server's response message is consumed. This typically means that `dblink_is_busy` or `dblink_get_result` should be called prior to `dblink_error_message`, so that any error generated by the asynchronous query will be visible.

Examples

```
SELECT dblink_error_message('dtest1');
```

dblink_send_query

`dblink_send_query` — sends an async query to a remote database

Synopsis

```
dblink_send_query(text connname, text sql) returns int
```

Description

`dblink_send_query` sends a query to be executed asynchronously, that is, without immediately waiting for the result. There must not be an async query already in progress on the connection.

After successfully dispatching an async query, completion status can be checked with `dblink_is_busy`, and the results are ultimately collected with `dblink_get_result`. It is also possible to attempt to cancel an active async query using `dblink_cancel_query`.

Arguments

connname

Name of the connection to use.

sql

The SQL statement that you wish to execute in the remote database, for example `select * from pg_class`.

Return Value

Returns 1 if the query was successfully dispatched, 0 otherwise.

Examples

```
SELECT dblink_send_query('dtest1', 'SELECT * FROM foo WHERE f1 < 3');
```

dblink_is_busy

`dblink_is_busy` — checks if connection is busy with an async query

Synopsis

```
dblink_is_busy(text connname) returns int
```

Description

`dblink_is_busy` tests whether an async query is in progress.

Arguments

connname

Name of the connection to check.

Return Value

Returns 1 if connection is busy, 0 if it is not busy. If this function returns 0, it is guaranteed that `dblink_get_result` will not block.

Examples

```
SELECT dblink_is_busy('dtest1');
```

dblink_get_notify

`dblink_get_notify` — retrieve async notifications on a connection

Synopsis

```
dblink_get_notify() returns setof (notify_name text, be_pid int, extra text)
dblink_get_notify(text connname) returns setof (notify_name text, be_pid int, extra
text)
```

Description

`dblink_get_notify` retrieves notifications on either the unnamed connection, or on a named connection if specified. To receive notifications via `dblink`, `LISTEN` must first be issued, using `dblink_exec`. For details see [LISTEN](#) and [NOTIFY](#).

Arguments

connname

The name of a named connection to get notifications on.

Return Value

Returns `setof (notify_name text, be_pid int, extra text)`, or an empty set if none.

Examples

```
SELECT dblink_exec('LISTEN virtual');
 dblink_exec
-----
LISTEN
(1 row)
```

```
SELECT * FROM dblink_get_notify();
 notify_name | be_pid | extra
-----+-----+-----
(0 rows)
```

```
NOTIFY virtual;
NOTIFY
```

```
SELECT * FROM dblink_get_notify();
 notify_name | be_pid | extra
-----+-----+-----
virtual      |    1229 |
(1 row)
```

dblink_get_result

`dblink_get_result` — gets an async query result

Synopsis

`dblink_get_result(text connname [, bool fail_on_error])` returns setof record

Description

`dblink_get_result` collects the results of an asynchronous query previously sent with `dblink_send_query`. If the query is not already completed, `dblink_get_result` will wait until it is.

Arguments

connname

Name of the connection to use.

fail_on_error

If true (the default when omitted) then an error thrown on the remote side of the connection causes an error to also be thrown locally. If false, the remote error is locally reported as a NOTICE, and the function returns no rows.

Return Value

For an async query (that is, an SQL statement returning rows), the function returns the row(s) produced by the query. To use this function, you will need to specify the expected set of columns, as previously discussed for `dblink`.

For an async command (that is, an SQL statement not returning rows), the function returns a single row with a single text column containing the command's status string. It is still necessary to specify that the result will have a single text column in the calling `FROM` clause.

Notes

This function *must* be called if `dblink_send_query` returned 1. It must be called once for each query sent, and one additional time to obtain an empty set result, before the connection can be used again.

When using `dblink_send_query` and `dblink_get_result`, `dblink` fetches the entire remote query result before returning any of it to the local query processor. If the query returns a large number of rows, this can result in transient memory bloat in the local session. It may be better to open such a query as a cursor with `dblink_open` and then fetch a manageable number of rows at a time. Alternatively, use plain `dblink()`, which avoids memory bloat by spooling large result sets to disk.

Examples

```
contrib_regression=# SELECT dblink_connect('dtest1', 'dbname=contrib_regression');
dblink_connect
-----
OK
(1 row)

contrib_regression=# SELECT * FROM
contrib_regression-# dblink_send_query('dtest1', 'select * from foo where f1 < 3') AS
t1;
t1
----
1
(1 row)
```

```
contrib_regression=# SELECT * FROM dblink_get_result('dtest1') AS t1(f1 int, f2 text,  
f3 text[]);
```

f1	f2	f3
0	a	{a0,b0,c0}
1	b	{a1,b1,c1}
2	c	{a2,b2,c2}

(3 rows)

```
contrib_regression=# SELECT * FROM dblink_get_result('dtest1') AS t1(f1 int, f2 text,  
f3 text[]);
```

f1	f2	f3

(0 rows)

```
contrib_regression=# SELECT * FROM  
contrib_regression=# dblink_send_query('dtest1', 'select * from foo where f1 < 3;  
select * from foo where f1 > 6') AS t1;
```

t1
1

(1 row)

```
contrib_regression=# SELECT * FROM dblink_get_result('dtest1') AS t1(f1 int, f2 text,  
f3 text[]);
```

f1	f2	f3
0	a	{a0,b0,c0}
1	b	{a1,b1,c1}
2	c	{a2,b2,c2}

(3 rows)

```
contrib_regression=# SELECT * FROM dblink_get_result('dtest1') AS t1(f1 int, f2 text,  
f3 text[]);
```

f1	f2	f3
7	h	{a7,b7,c7}
8	i	{a8,b8,c8}
9	j	{a9,b9,c9}
10	k	{a10,b10,c10}

(4 rows)

```
contrib_regression=# SELECT * FROM dblink_get_result('dtest1') AS t1(f1 int, f2 text,  
f3 text[]);
```

f1	f2	f3

(0 rows)

dblink_cancel_query

`dblink_cancel_query` — cancels any active query on the named connection

Synopsis

```
dblink_cancel_query(text connname) returns text
```

Description

`dblink_cancel_query` attempts to cancel any query that is in progress on the named connection. Note that this is not certain to succeed (since, for example, the remote query might already have finished). A cancel request simply improves the odds that the query will fail soon. You must still complete the normal query protocol, for example by calling `dblink_get_result`.

Arguments

connname

Name of the connection to use.

Return Value

Returns `OK` if the cancel request has been sent, or the text of an error message on failure.

Examples

```
SELECT dblink_cancel_query('dtest1');
```

dblink_get_pkey

`dblink_get_pkey` — returns the positions and field names of a relation's primary key fields

Synopsis

`dblink_get_pkey(text relname)` returns `setof dblink_pkey_results`

Description

`dblink_get_pkey` provides information about the primary key of a relation in the local database. This is sometimes useful in generating queries to be sent to remote databases.

Arguments

relname

Name of a local relation, for example `foo` or `myschema.mytab`. Include double quotes if the name is mixed-case or contains special characters, for example `"FooBar"`; without quotes, the string will be folded to lower case.

Return Value

Returns one row for each primary key field, or no rows if the relation has no primary key. The result row type is defined as

```
CREATE TYPE dblink_pkey_results AS (position int, colname text);
```

The `position` column simply runs from 1 to *N*; it is the number of the field within the primary key, not the number within the table's columns.

Examples

```
CREATE TABLE foobar (  
    f1 int,  
    f2 int,  
    f3 int,  
    PRIMARY KEY (f1, f2, f3)  
);  
CREATE TABLE  
  
SELECT * FROM dblink_get_pkey('foobar');  
 position | colname  
-----+-----  
        1 | f1  
        2 | f2  
        3 | f3  
(3 rows)
```

dblink_build_sql_insert

`dblink_build_sql_insert` — builds an `INSERT` statement using a local tuple, replacing the primary key field values with alternative supplied values

Synopsis

```
dblink_build_sql_insert(text relname,  
                        int2vector primary_key_attnums,  
                        integer num_primary_key_atts,  
                        text[] src_pk_att_vals_array,  
                        text[] tgt_pk_att_vals_array) returns text
```

Description

`dblink_build_sql_insert` can be useful in doing selective replication of a local table to a remote database. It selects a row from the local table based on primary key, and then builds an SQL `INSERT` command that will duplicate that row, but with the primary key values replaced by the values in the last argument. (To make an exact copy of the row, just specify the same values for the last two arguments.)

Arguments

relname

Name of a local relation, for example `foo` or `myschema.mytab`. Include double quotes if the name is mixed-case or contains special characters, for example `"FooBar"`; without quotes, the string will be folded to lower case.

primary_key_attnums

Attribute numbers (1-based) of the primary key fields, for example `1 2`.

num_primary_key_atts

The number of primary key fields.

src_pk_att_vals_array

Values of the primary key fields to be used to look up the local tuple. Each field is represented in text form. An error is thrown if there is no local row with these primary key values.

tgt_pk_att_vals_array

Values of the primary key fields to be placed in the resulting `INSERT` command. Each field is represented in text form.

Return Value

Returns the requested SQL statement as text.

Notes

As of PostgreSQL 9.0, the attribute numbers in *primary_key_attnums* are interpreted as logical column numbers, corresponding to the column's position in `SELECT * FROM relname`. Previous versions interpreted the numbers as physical column positions. There is a difference if any column(s) to the left of the indicated column have been dropped during the lifetime of the table.

Examples

```
SELECT dblink_build_sql_insert('foo', '1 2', 2, '{"1", "a"}', '{"1", "b''a"}');  
       dblink_build_sql_insert
```

Additional Supplied Modules
and Extensions Shipped in
postgrespro-std-16-contrib

```
INSERT INTO foo(f1,f2,f3) VALUES('1','b' 'a','1')
(1 row)
```

dblink_build_sql_delete

`dblink_build_sql_delete` — builds a DELETE statement using supplied values for primary key field values

Synopsis

```
dblink_build_sql_delete(text relname,  
                        int2vector primary_key_attnums,  
                        integer num_primary_key_atts,  
                        text[] tgt_pk_att_vals_array) returns text
```

Description

`dblink_build_sql_delete` can be useful in doing selective replication of a local table to a remote database. It builds an SQL DELETE command that will delete the row with the given primary key values.

Arguments

relname

Name of a local relation, for example `foo` or `myschema.mytab`. Include double quotes if the name is mixed-case or contains special characters, for example `"FooBar"`; without quotes, the string will be folded to lower case.

primary_key_attnums

Attribute numbers (1-based) of the primary key fields, for example `1 2`.

num_primary_key_atts

The number of primary key fields.

tgt_pk_att_vals_array

Values of the primary key fields to be used in the resulting DELETE command. Each field is represented in text form.

Return Value

Returns the requested SQL statement as text.

Notes

As of PostgreSQL 9.0, the attribute numbers in *primary_key_attnums* are interpreted as logical column numbers, corresponding to the column's position in `SELECT * FROM relname`. Previous versions interpreted the numbers as physical column positions. There is a difference if any column(s) to the left of the indicated column have been dropped during the lifetime of the table.

Examples

```
SELECT dblink_build_sql_delete('MyFoo', '1 2', 2, '{"1", "b"}');  
      dblink_build_sql_delete  
-----  
DELETE FROM "MyFoo" WHERE f1='1' AND f2='b'  
(1 row)
```

dblink_build_sql_update

`dblink_build_sql_update` — builds an UPDATE statement using a local tuple, replacing the primary key field values with alternative supplied values

Synopsis

```
dblink_build_sql_update(text relname,  
                        int2vector primary_key_attnums,  
                        integer num_primary_key_atts,  
                        text[] src_pk_att_vals_array,  
                        text[] tgt_pk_att_vals_array) returns text
```

Description

`dblink_build_sql_update` can be useful in doing selective replication of a local table to a remote database. It selects a row from the local table based on primary key, and then builds an SQL UPDATE command that will duplicate that row, but with the primary key values replaced by the values in the last argument. (To make an exact copy of the row, just specify the same values for the last two arguments.) The UPDATE command always assigns all fields of the row — the main difference between this and `dblink_build_sql_insert` is that it's assumed that the target row already exists in the remote table.

Arguments

relname

Name of a local relation, for example `foo` or `myschema.mytab`. Include double quotes if the name is mixed-case or contains special characters, for example `"FooBar"`; without quotes, the string will be folded to lower case.

primary_key_attnums

Attribute numbers (1-based) of the primary key fields, for example `1 2`.

num_primary_key_atts

The number of primary key fields.

src_pk_att_vals_array

Values of the primary key fields to be used to look up the local tuple. Each field is represented in text form. An error is thrown if there is no local row with these primary key values.

tgt_pk_att_vals_array

Values of the primary key fields to be placed in the resulting UPDATE command. Each field is represented in text form.

Return Value

Returns the requested SQL statement as text.

Notes

As of PostgreSQL 9.0, the attribute numbers in *primary_key_attnums* are interpreted as logical column numbers, corresponding to the column's position in `SELECT * FROM relname`. Previous versions interpreted the numbers as physical column positions. There is a difference if any column(s) to the left of the indicated column have been dropped during the lifetime of the table.

Examples

```
SELECT dblink_build_sql_update('foo', '1 2', 2, '{"1", "a"}', '{"1", "b"}');
```

Additional Supplied Modules
and Extensions Shipped in
postgrespro-std-16-contrib

dblink_build_sql_update

```
UPDATE foo SET f1='1',f2='b',f3='1' WHERE f1='1' AND f2='b'
(1 row)
```

F.16. dict_int — example full-text search dictionary for integers

`dict_int` is an example of an add-on dictionary template for full-text search. The motivation for this example dictionary is to control the indexing of integers (signed and unsigned), allowing such numbers to be indexed while preventing excessive growth in the number of unique words, which greatly affects the performance of searching.

This module is considered “trusted”, that is, it can be installed by non-superusers who have `CREATE` privilege on the current database.

F.16.1. Configuration

The dictionary accepts three options:

- The `maxlen` parameter specifies the maximum number of digits allowed in an integer word. The default value is 6.
- The `rejectlong` parameter specifies whether an overlength integer should be truncated or ignored. If `rejectlong` is `false` (the default), the dictionary returns the first `maxlen` digits of the integer. If `rejectlong` is `true`, the dictionary treats an overlength integer as a stop word, so that it will not be indexed. Note that this also means that such an integer cannot be searched for.
- The `absval` parameter specifies whether leading “+” or “-” signs should be removed from integer words. The default is `false`. When `true`, the sign is removed before `maxlen` is applied.

F.16.2. Usage

Installing the `dict_int` extension creates a text search template `intdict_template` and a dictionary `intdict` based on it, with the default parameters. You can alter the parameters, for example

```
mydb# ALTER TEXT SEARCH DICTIONARY intdict (MAXLEN = 4, REJECTLONG = true);
ALTER TEXT SEARCH DICTIONARY
```

or create new dictionaries based on the template.

To test the dictionary, you can try

```
mydb# select ts_lexize('intdict', '12345678');
ts_lexize
-----
{123456}
```

but real-world usage will involve including it in a text search configuration as described in [Chapter 12](#). That might look like this:

```
ALTER TEXT SEARCH CONFIGURATION english
    ALTER MAPPING FOR int, uint WITH intdict;
```

F.17. dict_xsyn — example synonym full-text search dictionary

`dict_xsyn` (Extended Synonym Dictionary) is an example of an add-on dictionary template for full-text search. This dictionary type replaces words with groups of their synonyms, and so makes it possible to search for a word using any of its synonyms.

F.17.1. Configuration

A `dict_xsyn` dictionary accepts the following options:

- `matchorig` controls whether the original word is accepted by the dictionary. Default is `true`.
- `matchsynonyms` controls whether the synonyms are accepted by the dictionary. Default is `false`.
- `keeporig` controls whether the original word is included in the dictionary's output. Default is `true`.
- `keepsynonyms` controls whether the synonyms are included in the dictionary's output. Default is `true`.
- `rules` is the base name of the file containing the list of synonyms. This file must be stored in `$SHAREDIR/tsearch_data/` (where `$SHAREDIR` means the Postgres Pro installation's shared-data directory). Its name must end in `.rules` (which is not to be included in the `rules` parameter).

The rules file has the following format:

- Each line represents a group of synonyms for a single word, which is given first on the line. Synonyms are separated by whitespace, thus:

```
word syn1 syn2 syn3
```
- The sharp (`#`) sign is a comment delimiter. It may appear at any position in a line. The rest of the line will be skipped.

Look at `xsyn_sample.rules`, which is installed in `$SHAREDIR/tsearch_data/`, for an example.

F.17.2. Usage

Installing the `dict_xsyn` extension creates a text search template `xsyn_template` and a dictionary `xsyn` based on it, with default parameters. You can alter the parameters, for example

```
mydb# ALTER TEXT SEARCH DICTIONARY xsyn (RULES='my_rules', KEEPORIG=false);
ALTER TEXT SEARCH DICTIONARY
```

or create new dictionaries based on the template.

To test the dictionary, you can try

```
mydb=# SELECT ts_lexize('xsyn', 'word');
       ts_lexize
-----
{syn1,syn2,syn3}
```

```
mydb# ALTER TEXT SEARCH DICTIONARY xsyn (RULES='my_rules', KEEPORIG=true);
ALTER TEXT SEARCH DICTIONARY
```

```
mydb=# SELECT ts_lexize('xsyn', 'word');
       ts_lexize
-----
{word,syn1,syn2,syn3}
```

```
mydb# ALTER TEXT SEARCH DICTIONARY xsyn (RULES='my_rules', KEEPORIG=false,
MATCHSYNONYMS=true);
```

```
ALTER TEXT SEARCH DICTIONARY
```

```
mydb=# SELECT ts_lexize('xsyn', 'syn1');
       ts_lexize
```

```
-----
{syn1,syn2,syn3}
```

```
mydb# ALTER TEXT SEARCH DICTIONARY xsyn (RULES='my_rules', KEEPORIG=true,
      MATCHORIG=false, KEEPSYNONYMS=false);
```

```
ALTER TEXT SEARCH DICTIONARY
```

```
mydb=# SELECT ts_lexize('xsyn', 'syn1');
       ts_lexize
```

```
-----
{word}
```

Real-world usage will involve including it in a text search configuration as described in [Chapter 12](#). That might look like this:

```
ALTER TEXT SEARCH CONFIGURATION english
```

```
    ALTER MAPPING FOR word, asciiword WITH xsyn, english_stem;
```

F.18. dump_stat — functions to backup and recover the pg_statistic table

The `dump_stat` module provides functions that allow you to backup and recover the contents of the `pg_statistic` table. When performing a dump/restore, you can use `dump_stat` to migrate the original statistics to the new server instead of running the `ANALYZE` command for the whole database cluster, which can significantly reduce downtime for large databases. The `dump_statistic` function generates `INSERT` statements which can later be applied to a compatible database. To successfully restore statistical data, you must install the extension on both the original and the recipient servers since these statements rely on the provided `dump_stat` functions.

Note that the definition of the `pg_statistic` table might change occasionally, which means that generated dump might be incompatible with future releases of Postgres Pro.

F.18.1. Installation

The `dump_stat` extension is included into Postgres Pro. Once you have Postgres Pro installed, you must execute the `CREATE EXTENSION` command to enable `dump_stat`, as follows:

```
CREATE EXTENSION dump_stat;
```

F.18.2. Functions

`anyarray_to_text(array anyarray)` returns text

Returns the given array as text.

`dump_statistic()` returns setof text

`dump_statistic` dumps the contents of the `pg_statistic` system catalog. It produces an `INSERT` statement per each tuple of the `pg_statistic`, excluding the ones that contain statistical data for tables in the `information_schema` and `pg_catalog` schemas.

The `INSERT` statement takes form of

```
WITH upsert as (  
  UPDATE pg_catalog.pg_statistic SET column_name = expression [, ...]  
  WHERE starelid = t_relname::regclass  
    AND to_attnum(t_relname, staattnum) = t_attnum  
    AND to_atttype(t_relname, staattnum) = t_atttype  
    AND stainherit = t_stainherit  
  RETURNING *)  
ins as (  
  SELECT expression [, ...]  
  WHERE NOT EXISTS (SELECT * FROM upsert)  
    AND to_attnum(t_relname, t_attnum) IS NOT NULL  
    AND to_atttype(t_relname, t_attnum) = t_atttype)  
INSERT INTO pg_catalog.pg_statistic SELECT * FROM ins;
```

where *expression* can be one of:

```
array_in(array_text, type_name::regtype::oid, -1)  
value::type_name
```

To save the produced statements, redirect the `psql` output into a file using standard `psql` options. For details on the available `psql` options, see [psql](#). Meta-commands starting with a backslash are not supported.

For example, to save statistics for the `dbname` database into a `dump_stat.sql` file, run:

```
$ psql -XAtq -c "SELECT dump_statistic()" dbname > dump_stat.sql
```

`dump_statistic(schema_name text)` returns setof text

`dump_statistic` dumps the contents of the `pg_statistic` system catalog. It produces an INSERT statement per each tuple of the `pg_statistic` that relates to some table in the `schema_name` schema.

`dump_statistic(schema_name text, table_name text)` returns setof text

`dump_statistic` dumps the contents of the `pg_statistic` system catalog. It produces an INSERT statement per each tuple of the `pg_statistic` that relates to the specified `schema_name.table_name` table.

`dump_statistic(relation regclass)` returns setof text

`dump_statistic` dumps the contents of the `pg_statistic` system catalog. It produces an INSERT statement per each tuple of the `pg_statistic` that contains statistical data for the specified relation.

`to_schema_qualified_operator(opid oid)` returns text

Fetches the schema-qualified operator name by operator id `opid`. For example:

```
test=# SELECT to_schema_qualified_operator('+(int,int)::regoperator');
           to_schema_qualified_operator
-----
pg_catalog.+(pg_catalog.int4, pg_catalog.int4)
(1 row)
```

`to_schema_qualified_type(typid oid)` returns text

Fetches the schema-qualified type name by type id `typid`.

`to_schema_qualified_relation(relid oid)` returns text

Fetches the schema-qualified relation name by relation id `relid`.

`anyarray_elemtype(arr anyarray)` returns oid

Returns the element type of the given array as oid. For example:

```
test=# SELECT anyarray_elemtype(array_in('{1,2,3}', 'int'::regtype, -1));
           anyarray_elemtype
-----
                        23
(1 row)
```

`to_attname(relation regclass, colnum int2)` returns text

Given a relation name `relation` and a column number `colnum`, returns the column name as text.

`to_attnum(relation regclass, col text)` returns int2

Given a relation name `relation` and a column name `col`, returns the column number as int2.

`to_atttype(relation regclass, col text)` returns text

Given a relation name `relation` and a column name `col`, returns the schema-qualified column type as text.

`to_atttype(relation regclass, colnum int2)` returns text

Given a relation name `relation` and a column number `colnum`, returns the schema-qualified column type as text.

`to_namespace(nsp text)` returns oid

`to_namespace` duplicates the behavior of the cast to the `regnamespace` type, which is not present in the PostgreSQL 9.4 release (and prior releases). This function returns the oid of the given schema.

Additional Supplied Modules
and Extensions Shipped in
postgrespro-std-16-contrib

`get_namespace(relation oid)` returns oid

`get_namespace` returns the schema of the given relation as oid.

F.19. earthdistance — calculate great-circle distances

The `earthdistance` module provides two different approaches to calculating great circle distances on the surface of the Earth. The one described first depends on the `cube` module. The second one is based on the built-in `point` data type, using longitude and latitude for the coordinates.

In this module, the Earth is assumed to be perfectly spherical. (If that's too inaccurate for you, you might want to look at the [PostGIS](#) project.)

The `cube` module must be installed before `earthdistance` can be installed (although you can use the `CASCADE` option of `CREATE EXTENSION` to install both in one command).

Caution

It is strongly recommended that `earthdistance` and `cube` be installed in the same schema, and that that schema be one for which `CREATE` privilege has not been and will not be granted to any untrusted users. Otherwise there are installation-time security hazards if `earthdistance`'s schema contains objects defined by a hostile user. Furthermore, when using `earthdistance`'s functions after installation, the entire search path should contain only trusted schemas.

F.19.1. Cube-Based Earth Distances

Data is stored in cubes that are points (both corners are the same) using 3 coordinates representing the x, y, and z distance from the center of the Earth. A [domain](#) `earth` over type `cube` is provided, which includes constraint checks that the value meets these restrictions and is reasonably close to the actual surface of the Earth.

The radius of the Earth is obtained from the `earth()` function. It is given in meters. But by changing this one function you can change the module to use some other units, or to use a different value of the radius that you feel is more appropriate.

This package has applications to astronomical databases as well. Astronomers will probably want to change `earth()` to return a radius of `180/pi()` so that distances are in degrees.

Functions are provided to support input in latitude and longitude (in degrees), to support output of latitude and longitude, to calculate the great circle distance between two points and to easily specify a bounding box usable for index searches.

The provided functions are shown in [Table F.9](#).

Table F.9. Cube-Based Earthdistance Functions

Function	Description
<code>earth() → float8</code>	Returns the assumed radius of the Earth.
<code>sec_to_gc (float8) → float8</code>	Converts the normal straight line (secant) distance between two points on the surface of the Earth to the great circle distance between them.
<code>gc_to_sec (float8) → float8</code>	Converts the great circle distance between two points on the surface of the Earth to the normal straight line (secant) distance between them.
<code>ll_to_earth (float8, float8) → earth</code>	Returns the location of a point on the surface of the Earth given its latitude (argument 1) and longitude (argument 2) in degrees.

Function	Description
<code>latitude (earth) → float8</code>	Returns the latitude in degrees of a point on the surface of the Earth.
<code>longitude (earth) → float8</code>	Returns the longitude in degrees of a point on the surface of the Earth.
<code>earth_distance (earth, earth) → float8</code>	Returns the great circle distance between two points on the surface of the Earth.
<code>earth_box (earth, float8) → cube</code>	Returns a box suitable for an indexed search using the <code>cube @></code> operator for points within a given great circle distance of a location. Some points in this box are further than the specified great circle distance from the location, so a second check using <code>earth_distance</code> should be included in the query.

F.19.2. Point-Based Earth Distances

The second part of the module relies on representing Earth locations as values of type `point`, in which the first component is taken to represent longitude in degrees, and the second component is taken to represent latitude in degrees. Points are taken as (longitude, latitude) and not vice versa because longitude is closer to the intuitive idea of x-axis and latitude to y-axis.

A single operator is provided, shown in [Table F.10](#).

Table F.10. Point-Based Earthdistance Operators

Operator	Description
<code>point <@> point → float8</code>	Computes the distance in statute miles between two points on the Earth's surface.

Note that unlike the `cube`-based part of the module, units are hardwired here: changing the `earth()` function will not affect the results of this operator.

One disadvantage of the longitude/latitude representation is that you need to be careful about the edge conditions near the poles and near +/- 180 degrees of longitude. The `cube`-based representation avoids these discontinuities.

F.20. fasttrun — a transaction unsafe function to truncate temporary tables

The `fasttrun` module provides transaction unsafe function to truncate temporary tables without growing `pg_class` size.

This module is required for 1C Enterprise support.

Fast truncate operation is not transactional, so its results cannot be rolled back and become immediately visible in all sessions regardless of isolation level.

F.20.1. Function

There is a function call example:

```
select fasttruncate('TABLE_NAME');
```

F.20.2. Test example

For tests you can use this example:

```
create or replace function f() returns void as $$
begin
  for i in 1..1000
  loop
    PERFORM fasttruncate('tt1');
  end loop;
end;
$$ language plpgsql;
```

Teodor Sigaev <teodor@sigaev.ru>

F.21. file_fdw — access data files in the server's file system

The `file_fdw` module provides the foreign-data wrapper `file_fdw`, which can be used to access data files in the server's file system, or to execute programs on the server and read their output. The data file or program output must be in a format that can be read by `COPY FROM`; see [COPY](#) for details. Access to data files is currently read-only.

A foreign table created using this wrapper can have the following options:

`filename`

Specifies the file to be read. Relative paths are relative to the data directory. Either `filename` or `program` must be specified, but not both.

`program`

Specifies the command to be executed. The standard output of this command will be read as though `COPY FROM PROGRAM` were used. Either `program` or `filename` must be specified, but not both.

`format`

Specifies the data format, the same as `COPY`'s `FORMAT` option.

`header`

Specifies whether the data has a header line, the same as `COPY`'s `HEADER` option.

`delimiter`

Specifies the data delimiter character, the same as `COPY`'s `DELIMITER` option.

`quote`

Specifies the data quote character, the same as `COPY`'s `QUOTE` option.

`escape`

Specifies the data escape character, the same as `COPY`'s `ESCAPE` option.

`null`

Specifies the data null string, the same as `COPY`'s `NULL` option.

`encoding`

Specifies the data encoding, the same as `COPY`'s `ENCODING` option.

Note that while `COPY` allows options such as `HEADER` to be specified without a corresponding value, the foreign table option syntax requires a value to be present in all cases. To activate `COPY` options typically written without a value, you can pass the value `TRUE`, since all such options are Booleans.

A column of a foreign table created using this wrapper can have the following options:

`force_not_null`

This is a Boolean option. If true, it specifies that values of the column should not be matched against the null string (that is, the table-level `null` option). This has the same effect as listing the column in `COPY`'s `FORCE_NOT_NULL` option.

`force_null`

This is a Boolean option. If true, it specifies that values of the column which match the null string are returned as `NULL` even if the value is quoted. Without this option, only unquoted values matching the

null string are returned as NULL. This has the same effect as listing the column in COPY's FORCE_NULL option.

COPY's FORCE_QUOTE option is currently not supported by file_fdw.

These options can only be specified for a foreign table or its columns, not in the options of the file_fdw foreign-data wrapper, nor in the options of a server or user mapping using the wrapper.

Changing table-level options requires being a superuser or having the privileges of the role pg_read_server_files (to use a filename) or the role pg_execute_server_program (to use a program), for security reasons: only certain users should be able to control which file is read or which program is run. In principle regular users could be allowed to change the other options, but that's not supported at present.

When specifying the program option, keep in mind that the option string is executed by the shell. If you need to pass any arguments to the command that come from an untrusted source, you must be careful to strip or escape any characters that might have special meaning to the shell. For security reasons, it is best to use a fixed command string, or at least avoid passing any user input in it.

For a foreign table using file_fdw, EXPLAIN shows the name of the file to be read or program to be run. For a file, unless COSTS OFF is specified, the file size (in bytes) is shown as well.

Example F.5. Create a Foreign Table for Postgres Pro CSV Logs

One of the obvious uses for file_fdw is to make the Postgres Pro activity log available as a table for querying. To do this, first you must be [logging to a CSV file](#), which here we will call pglog.csv. First, install file_fdw as an extension:

```
CREATE EXTENSION file_fdw;
```

Then create a foreign server:

```
CREATE SERVER pglog FOREIGN DATA WRAPPER file_fdw;
```

Now you are ready to create the foreign data table. Using the CREATE FOREIGN TABLE command, you will need to define the columns for the table, the CSV file name, and its format:

```
CREATE FOREIGN TABLE pglog (  
    log_time timestamp(3) with time zone,  
    user_name text,  
    database_name text,  
    process_id integer,  
    connection_from text,  
    session_id text,  
    session_line_num bigint,  
    command_tag text,  
    session_start_time timestamp with time zone,  
    virtual_transaction_id text,  
    transaction_id bigint,  
    error_severity text,  
    sql_state_code text,  
    message text,  
    detail text,  
    hint text,  
    internal_query text,  
    internal_query_pos integer,  
    context text,  
    query text,  
    query_pos integer,  
    location text,  
    application_name text,
```

```
backend_type text,  
leader_pid integer,  
query_id bigint  
) SERVER pglog  
OPTIONS ( filename 'log/pglog.csv', format 'csv' );
```

That's it — now you can query your log directly. In production, of course, you would need to define some way to deal with log rotation.

F.22. fulleq — an additional equivalence operator for compatibility with Microsoft SQL Server

The `fulleq` module provides additional equivalence operator for compatibility with Microsoft SQL Server.

This module is required for 1C Enterprise support.

F.22.1. Overview

The Postgres Pro equivalence operator is defined to return NULL when both operands are NULLs. However, the Microsoft SQL Servers family traditionally defines other semantic for equivalence operator, where operator returns TRUE in the case of both nulled operands. This module provides such operator with MS SQL semantic.

F.22.2. Operator `fulleq`

The `==` operator is defined for the following data types:

- `bool`
- `bytea`
- `char`
- `name`
- `int2`
- `int4`
- `int8`
- `int2vector`
- `text`
- `oid`
- `xid`
- `cid`
- `oidvector`
- `float4`
- `float8`
- `abstime`
- `reltime`
- `macaddr`
- `inet`
- `cidr`
- `varchar`
- `date`
- `time`
- `timestamp`
- `timestampz`
- `interval`
- `timetz`

F.22.3. Authors

Teodor Sigaev <teodor@sigaev.ru>

F.23. fuzzystmatch — determine string similarities and distance

The `fuzzystmatch` module provides several functions to determine similarities and distance between strings.

Caution

At present, the `soundex`, `metaphone`, `dmetaphone`, and `dmetaphone_alt` functions do not work well with multibyte encodings (such as UTF-8). Use `daitch_mokotoff` or `levenshtein` with such data.

This module is considered “trusted”, that is, it can be installed by non-superusers who have `CREATE` privilege on the current database.

F.23.1. Soundex

The Soundex system is a method of matching similar-sounding names by converting them to the same code. It was initially used by the United States Census in 1880, 1900, and 1910. Note that Soundex is not very useful for non-English names.

The `fuzzystmatch` module provides two functions for working with Soundex codes:

```
soundex(text) returns text  
difference(text, text) returns int
```

The `soundex` function converts a string to its Soundex code. The `difference` function converts two strings to their Soundex codes and then reports the number of matching code positions. Since Soundex codes have four characters, the result ranges from zero to four, with zero being no match and four being an exact match. (Thus, the function is misnamed — `similarity` would have been a better name.)

Here are some usage examples:

```
SELECT soundex('hello world!');  
  
SELECT soundex('Anne'), soundex('Ann'), difference('Anne', 'Ann');  
SELECT soundex('Anne'), soundex('Andrew'), difference('Anne', 'Andrew');  
SELECT soundex('Anne'), soundex('Margaret'), difference('Anne', 'Margaret');  
  
CREATE TABLE s (nm text);  
  
INSERT INTO s VALUES ('john');  
INSERT INTO s VALUES ('joan');  
INSERT INTO s VALUES ('wobbly');  
INSERT INTO s VALUES ('jack');  
  
SELECT * FROM s WHERE soundex(nm) = soundex('john');  
  
SELECT * FROM s WHERE difference(s.nm, 'john') > 2;
```

F.23.2. Daitch-Mokotoff Soundex

Like the original Soundex system, Daitch-Mokotoff Soundex matches similar-sounding names by converting them to the same code. However, Daitch-Mokotoff Soundex is significantly more useful for non-English names than the original system. Major improvements over the original system include:

- The code is based on the first six meaningful letters rather than four.
- A letter or combination of letters maps into ten possible codes rather than seven.
- Where two consecutive letters have a single sound, they are coded as a single number.

- When a letter or combination of letters may have different sounds, multiple codes are emitted to cover all possibilities.

This function generates the Daitch-Mokotoff soundex codes for its input:

`daitch_mokotoff(source text)` returns `text[]`

The result may contain one or more codes depending on how many plausible pronunciations there are, so it is represented as an array.

Since a Daitch-Mokotoff soundex code consists of only 6 digits, *source* should be preferably a single word or name.

Here are some examples:

```
SELECT daitch_mokotoff('George');
       daitch_mokotoff
-----
 {595000}

SELECT daitch_mokotoff('John');
       daitch_mokotoff
-----
 {160000,460000}

SELECT daitch_mokotoff('Bierschbach');
               daitch_mokotoff
-----
 {794575,794574,794750,794740,745750,745740,747500,747400}

SELECT daitch_mokotoff('Schwarzenegger');
       daitch_mokotoff
-----
 {479465}
```

For matching of single names, returned text arrays can be matched directly using the `&&` operator: any overlap can be considered a match. A GIN index may be used for efficiency, see [Chapter 67](#) and this example:

```
CREATE TABLE s (nm text);
CREATE INDEX ix_s_dm ON s USING gin (daitch_mokotoff(nm)) WITH (fastupdate = off);

INSERT INTO s (nm) VALUES
 ('Schwarzenegger'),
 ('John'),
 ('James'),
 ('Steinman'),
 ('Steinmetz');

SELECT * FROM s WHERE daitch_mokotoff(nm) && daitch_mokotoff('Swartzenegger');
SELECT * FROM s WHERE daitch_mokotoff(nm) && daitch_mokotoff('Jane');
SELECT * FROM s WHERE daitch_mokotoff(nm) && daitch_mokotoff('Jens');
```

For indexing and matching of any number of names in any order, Full Text Search features can be used. See [Chapter 12](#) and this example:

```
CREATE FUNCTION soundex_tsvector(v_name text) RETURNS tsvector
BEGIN ATOMIC
    SELECT to_tsvector('simple',
                      string_agg(array_to_string(daitch_mokotoff(n), ' '), ' '))
```

```
FROM regexp_split_to_table(v_name, '\s+') AS n;
END;

CREATE FUNCTION soundex_tsquery(v_name text) RETURNS tsquery
BEGIN ATOMIC
    SELECT string_agg('(' || array_to_string(daitch_mokotoff(n), '|') || ')',
    '&')::tsquery
    FROM regexp_split_to_table(v_name, '\s+') AS n;
END;

CREATE TABLE s (nm text);
CREATE INDEX ix_s_txt ON s USING gin (soundex_tsvector(nm)) WITH (fastupdate = off);

INSERT INTO s (nm) VALUES
    ('John Doe'),
    ('Jane Roe'),
    ('Public John Q.'),
    ('George Best'),
    ('John Yamson');

SELECT * FROM s WHERE soundex_tsvector(nm) @@ soundex_tsquery('john');
SELECT * FROM s WHERE soundex_tsvector(nm) @@ soundex_tsquery('jane doe');
SELECT * FROM s WHERE soundex_tsvector(nm) @@ soundex_tsquery('john public');
SELECT * FROM s WHERE soundex_tsvector(nm) @@ soundex_tsquery('besst, giorgio');
SELECT * FROM s WHERE soundex_tsvector(nm) @@ soundex_tsquery('Jameson John');
```

If it is desired to avoid recalculation of soundex codes during index rechecks, an index on a separate column can be used instead of an index on an expression. A stored generated column can be used for this; see [Section 5.3](#).

F.23.3. Levenshtein

This function calculates the Levenshtein distance between two strings:

```
levenshtein(source text, target text, ins_cost int, del_cost int, sub_cost int) returns
int
levenshtein(source text, target text) returns int
levenshtein_less_equal(source text, target text, ins_cost int, del_cost int, sub_cost
int, max_d int) returns int
levenshtein_less_equal(source text, target text, max_d int) returns int
```

Both `source` and `target` can be any non-null string, with a maximum of 255 characters. The cost parameters specify how much to charge for a character insertion, deletion, or substitution, respectively. You can omit the cost parameters, as in the second version of the function; in that case they all default to 1.

`levenshtein_less_equal` is an accelerated version of the Levenshtein function for use when only small distances are of interest. If the actual distance is less than or equal to `max_d`, then `levenshtein_less_equal` returns the correct distance; otherwise it returns some value greater than `max_d`. If `max_d` is negative then the behavior is the same as `levenshtein`.

Examples:

```
test=# SELECT levenshtein('GUMBO', 'GAMBOL');
 levenshtein
-----
          2
(1 row)

test=# SELECT levenshtein('GUMBO', 'GAMBOL', 2, 1, 1);
```

```
levenshtein
-----
          3
(1 row)

test=# SELECT levenshtein_less_equal('extensive', 'exhaustive', 2);
 levenshtein_less_equal
-----
          3
(1 row)

test=# SELECT levenshtein_less_equal('extensive', 'exhaustive', 4);
 levenshtein_less_equal
-----
          4
(1 row)
```

F.23.4. Metaphone

Metaphone, like Soundex, is based on the idea of constructing a representative code for an input string. Two strings are then deemed similar if they have the same codes.

This function calculates the metaphone code of an input string:

`metaphone(source text, max_output_length int)` returns text

`source` has to be a non-null string with a maximum of 255 characters. `max_output_length` sets the maximum length of the output metaphone code; if longer, the output is truncated to this length.

Example:

```
test=# SELECT metaphone('GUMBO', 4);
 metaphone
-----
      KM
(1 row)
```

F.23.5. Double Metaphone

The Double Metaphone system computes two “sounds like” strings for a given input string — a “primary” and an “alternate”. In most cases they are the same, but for non-English names especially they can be a bit different, depending on pronunciation. These functions compute the primary and alternate codes:

`dmetaphone(source text)` returns text
`dmetaphone_alt(source text)` returns text

There is no length limit on the input strings.

Example:

```
test=# SELECT dmetaphone('gumbo');
 dmetaphone
-----
      KMP
(1 row)
```

F.24. hstore — hstore key/value datatype

This module implements the `hstore` data type for storing sets of key/value pairs within a single Postgres Pro value. This can be useful in various scenarios, such as rows with many attributes that are rarely examined, or semi-structured data. Keys and values are simply text strings.

This module is considered “trusted”, that is, it can be installed by non-superusers who have `CREATE` privilege on the current database.

F.24.1. hstore External Representation

The text representation of an `hstore`, used for input and output, includes zero or more `key => value` pairs separated by commas. Some examples:

```
k => v
foo => bar, baz => whatever
"1-a" => "anything at all"
```

The order of the pairs is not significant (and may not be reproduced on output). Whitespace between pairs or around the `=>` sign is ignored. Double-quote keys and values that include whitespace, commas, `=`s or `>`s. To include a double quote or a backslash in a key or value, escape it with a backslash.

Each key in an `hstore` is unique. If you declare an `hstore` with duplicate keys, only one will be stored in the `hstore` and there is no guarantee as to which will be kept:

```
SELECT 'a=>1,a=>2'::hstore;
 hstore
-----
"a"=>"1"
```

A value (but not a key) can be an SQL `NULL`. For example:

```
key => NULL
```

The `NULL` keyword is case-insensitive. Double-quote the `NULL` to treat it as the ordinary string “NULL”.

Note

Keep in mind that the `hstore` text format, when used for input, applies *before* any required quoting or escaping. If you are passing an `hstore` literal via a parameter, then no additional processing is needed. But if you're passing it as a quoted literal constant, then any single-quote characters and (depending on the setting of the `standard_conforming_strings` configuration parameter) backslash characters need to be escaped correctly. See [Section 4.1.2.1](#) for more on the handling of string constants.

On output, double quotes always surround keys and values, even when it's not strictly necessary.

F.24.2. hstore Operators and Functions

The operators provided by the `hstore` module are shown in [Table F.11](#), the functions in [Table F.12](#).

Table F.11. hstore Operators

Operator	Description	Example(s)
<code>hstore -> text → text</code>	Returns value associated with given key, or <code>NULL</code> if not present.	<code>'a=>x, b=>y'::hstore -> 'a' → x</code>
<code>hstore -> text [] → text []</code>	Returns values associated with given keys, or <code>NULL</code> if not present.	

Operator	Description	Example(s)
		'a=>x, b=>y, c=>z'::hstore -> ARRAY['c','a'] → {"z","x"}
hstore hstore → hstore	Concatenates two hstores.	'a=>b, c=>d'::hstore 'c=>x, d=>q'::hstore → "a"=>"b", "c"=>"x", "d"=>"q"
hstore ? text → boolean	Does hstore contain key?	'a=>1'::hstore ? 'a' → t
hstore ?& text[] → boolean	Does hstore contain all the specified keys?	'a=>1,b=>2'::hstore ?& ARRAY['a','b'] → t
hstore ? text[] → boolean	Does hstore contain any of the specified keys?	'a=>1,b=>2'::hstore ? ARRAY['b','c'] → t
hstore @> hstore → boolean	Does left operand contain right?	'a=>b, b=>1, c=>NULL'::hstore @> 'b=>1' → t
hstore <@ hstore → boolean	Is left operand contained in right?	'a=>c'::hstore <@ 'a=>b, b=>1, c=>NULL' → f
hstore - text → hstore	Deletes key from left operand.	'a=>1, b=>2, c=>3'::hstore - 'b'::text → "a"=>"1", "c"=>"3"
hstore - text[] → hstore	Deletes keys from left operand.	'a=>1, b=>2, c=>3'::hstore - ARRAY['a','b'] → "c"=>"3"
hstore - hstore → hstore	Deletes pairs from left operand that match pairs in the right operand.	'a=>1, b=>2, c=>3'::hstore - 'a=>4, b=>2'::hstore → "a"=>"1", "c"=>"3"
anyelement #= hstore → anyelement	Replaces fields in the left operand (which must be a composite type) with matching values from hstore.	ROW(1,3) #= 'f1=>11'::hstore → (11,3)
%% hstore → text[]	Converts hstore to an array of alternating keys and values.	%% 'a=>foo, b=>bar'::hstore → {a,foo,b,bar}
%# hstore → text[]	Converts hstore to a two-dimensional key/value array.	%# 'a=>foo, b=>bar'::hstore → {{a,foo},{b,bar}}

Table F.12. hstore Functions

Function	Description	Example(s)
<code>hstore (record) → hstore</code>	Constructs an <code>hstore</code> from a record or row.	<code>hstore(ROW(1,2)) → "f1"=>"1", "f2"=>"2"</code>
<code>hstore (text[]) → hstore</code>	Constructs an <code>hstore</code> from an array, which may be either a key/value array, or a two-dimensional array.	<code>hstore(ARRAY['a','1','b','2']) → "a"=>"1", "b"=>"2"</code> <code>hstore(ARRAY[['c','3'],['d','4']]) → "c"=>"3", "d"=>"4"</code>
<code>hstore (text[], text[]) → hstore</code>	Constructs an <code>hstore</code> from separate key and value arrays.	<code>hstore(ARRAY['a','b'], ARRAY['1','2']) → "a"=>"1", "b"=>"2"</code>
<code>hstore (text, text) → hstore</code>	Makes a single-item <code>hstore</code> .	<code>hstore('a', 'b') → "a"=>"b"</code>
<code>akeys (hstore) → text[]</code>	Extracts an <code>hstore</code> 's keys as an array.	<code>akeys('a=>1,b=>2') → {a,b}</code>
<code>skeys (hstore) → setof text</code>	Extracts an <code>hstore</code> 's keys as a set.	<code>skeys('a=>1,b=>2') →</code> <code>a</code> <code>b</code>
<code>avals (hstore) → text[]</code>	Extracts an <code>hstore</code> 's values as an array.	<code>avals('a=>1,b=>2') → {1,2}</code>
<code>svals (hstore) → setof text</code>	Extracts an <code>hstore</code> 's values as a set.	<code>svals('a=>1,b=>2') →</code> <code>1</code> <code>2</code>
<code>hstore_to_array (hstore) → text[]</code>	Extracts an <code>hstore</code> 's keys and values as an array of alternating keys and values.	<code>hstore_to_array('a=>1,b=>2') → {a,1,b,2}</code>
<code>hstore_to_matrix (hstore) → text[]</code>	Extracts an <code>hstore</code> 's keys and values as a two-dimensional array.	<code>hstore_to_matrix('a=>1,b=>2') → {{a,1},{b,2}}</code>
<code>hstore_to_json (hstore) → json</code>	Converts an <code>hstore</code> to a <code>json</code> value, converting all non-null values to JSON strings. This function is used implicitly when an <code>hstore</code> value is cast to <code>json</code> .	<code>hstore_to_json('"a key"=>1, b=>t, c=>null, d=>12345, e=>012345, f=>1.234, g=>2.345e+4') → {"a key": "1", "b": "t", "c": null, "d": "12345", "e": "012345", "f": "1.234", "g": "2.345e+4"}</code>

and Extensions Shipped in
postgrespro-std-16-contrib

Function	Description	Example(s)
<code>hstore_to_jsonb (hstore) → jsonb</code>	Converts an <code>hstore</code> to a <code>jsonb</code> value, converting all non-null values to JSON strings. This function is used implicitly when an <code>hstore</code> value is cast to <code>jsonb</code> .	<code>hstore_to_jsonb('"a key"=>1, b=>t, c=>null, d=>12345, e=>012345, f=>1.234, g=>2.345e+4') → {"a key": "1", "b": "t", "c": null, "d": "12345", "e": "012345", "f": "1.234", "g": "2.345e+4"}</code>
<code>hstore_to_json_loose (hstore) → json</code>	Converts an <code>hstore</code> to a <code>json</code> value, but attempts to distinguish numerical and Boolean values so they are unquoted in the JSON.	<code>hstore_to_json_loose('"a key"=>1, b=>t, c=>null, d=>12345, e=>012345, f=>1.234, g=>2.345e+4') → {"a key": 1, "b": true, "c": null, "d": 12345, "e": "012345", "f": 1.234, "g": 2.345e+4}</code>
<code>hstore_to_jsonb_loose (hstore) → jsonb</code>	Converts an <code>hstore</code> to a <code>jsonb</code> value, but attempts to distinguish numerical and Boolean values so they are unquoted in the JSON.	<code>hstore_to_jsonb_loose('"a key"=>1, b=>t, c=>null, d=>12345, e=>012345, f=>1.234, g=>2.345e+4') → {"a key": 1, "b": true, "c": null, "d": 12345, "e": "012345", "f": 1.234, "g": 2.345e+4}</code>
<code>slice (hstore, text[]) → hstore</code>	Extracts a subset of an <code>hstore</code> containing only the specified keys.	<code>slice('a=>1,b=>2,c=>3'::hstore, ARRAY['b','c','x']) → "b"=>"2", "c"=>"3"</code>
<code>each (hstore) → setof record (key text, value text)</code>	Extracts an <code>hstore</code> 's keys and values as a set of records.	<code>select * from each('a=>1,b=>2') →</code> <pre> key value -----+----- a 1 b 2 </pre>
<code>exist (hstore, text) → boolean</code>	Does <code>hstore</code> contain key?	<code>exist('a=>1', 'a') → t</code>
<code>defined (hstore, text) → boolean</code>	Does <code>hstore</code> contain a non-NULL value for key?	<code>defined('a=>NULL', 'a') → f</code>
<code>delete (hstore, text) → hstore</code>	Deletes pair with matching key.	<code>delete('a=>1,b=>2', 'b') → "a"=>"1"</code>
<code>delete (hstore, text[]) → hstore</code>	Deletes pairs with matching keys.	<code>delete('a=>1,b=>2,c=>3', ARRAY['a','b']) → "c"=>"3"</code>
<code>delete (hstore, hstore) → hstore</code>	Deletes pairs matching those in the second argument.	<code>delete('a=>1,b=>2', 'a=>4,b=>2'::hstore) → "a"=>"1"</code>
<code>populate_record (anyelement, hstore) → anyelement</code>		

Function	Description	Example(s)
	Replaces fields in the left operand (which must be a composite type) with matching values from <code>hstore</code> .	
	<code>populate_record(ROW(1,2), 'f1=>42'::hstore)</code>	<code>→ (42,2)</code>

In addition to these operators and functions, values of the `hstore` type can be subscripted, allowing them to act like associative arrays. Only a single subscript of type `text` can be specified; it is interpreted as a key and the corresponding value is fetched or stored. For example,

```
CREATE TABLE mytable (h hstore);
INSERT INTO mytable VALUES ('a=>b, c=>d');
SELECT h['a'] FROM mytable;
h
---
b
(1 row)
```

```
UPDATE mytable SET h['c'] = 'new';
SELECT h FROM mytable;
h
-----
"a"=>"b", "c"=>"new"
(1 row)
```

A subscripted fetch returns `NULL` if the subscript is `NULL` or that key does not exist in the `hstore`. (Thus, a subscripted fetch is not greatly different from the `->` operator.) A subscripted update fails if the subscript is `NULL`; otherwise, it replaces the value for that key, adding an entry to the `hstore` if the key does not already exist.

F.24.3. Indexes

`hstore` has GiST and GIN index support for the `@>`, `?`, `?&` and `?|` operators. For example:

```
CREATE INDEX hidx ON testhstore USING GIST (h);

CREATE INDEX hidx ON testhstore USING GIN (h);
```

`gist_hstore_ops` GiST opclass approximates a set of key/value pairs as a bitmap signature. Its optional integer parameter `siglen` determines the signature length in bytes. The default length is 16 bytes. Valid values of signature length are between 1 and 2024 bytes. Longer signatures lead to a more precise search (scanning a smaller fraction of the index and fewer heap pages), at the cost of a larger index.

Example of creating such an index with a signature length of 32 bytes:

```
CREATE INDEX hidx ON testhstore USING GIST (h gist_hstore_ops(siglen=32));
```

`hstore` also supports `btree` or `hash` indexes for the `=` operator. This allows `hstore` columns to be declared `UNIQUE`, or to be used in `GROUP BY`, `ORDER BY` or `DISTINCT` expressions. The sort ordering for `hstore` values is not particularly useful, but these indexes may be useful for equivalence lookups. Create indexes for `=` comparisons as follows:

```
CREATE INDEX hidx ON testhstore USING BTREE (h);

CREATE INDEX hidx ON testhstore USING HASH (h);
```

F.24.4. Examples

Add a key, or update an existing key with a new value:

```
UPDATE tab SET h['c'] = '3';
```

Another way to do the same thing is:

```
UPDATE tab SET h = h || hstore('c', '3');
```

If multiple keys are to be added or changed in one operation, the concatenation approach is more efficient than subscripting:

```
UPDATE tab SET h = h || hstore(array['q', 'w'], array['11', '12']);
```

Delete a key:

```
UPDATE tab SET h = delete(h, 'k1');
```

Convert a record to an `hstore`:

```
CREATE TABLE test (col1 integer, col2 text, col3 text);
INSERT INTO test VALUES (123, 'foo', 'bar');
```

```
SELECT hstore(t) FROM test AS t;
           hstore
```

```
-----
"col1"=>"123", "col2"=>"foo", "col3"=>"bar"
(1 row)
```

Convert an `hstore` to a predefined record type:

```
CREATE TABLE test (col1 integer, col2 text, col3 text);
```

```
SELECT * FROM populate_record(null::test,
                               '"col1"=>"456", "col2"=>"zzz"');
```

```
 col1 | col2 | col3
-----+-----+-----
  456 | zzz  |
(1 row)
```

Modify an existing record using the values from an `hstore`:

```
CREATE TABLE test (col1 integer, col2 text, col3 text);
INSERT INTO test VALUES (123, 'foo', 'bar');
```

```
SELECT (r).* FROM (SELECT t #= '"col3"=>"baz"' AS r FROM test t) s;
```

```
 col1 | col2 | col3
-----+-----+-----
  123 | foo  | baz
(1 row)
```

F.24.5. Statistics

The `hstore` type, because of its intrinsic liberality, could contain a lot of different keys. Checking for valid keys is the task of the application. The following examples demonstrate several techniques for checking keys and obtaining statistics.

Simple example:

```
SELECT * FROM each('aaa=>bq, b=>NULL, ""=>1');
```

Using a table:

```
CREATE TABLE stat AS SELECT (each(h)).key, (each(h)).value FROM testhstore;
```

Online statistics:

```
SELECT key, count(*) FROM
```

```
(SELECT (each(h)).key FROM testhstore) AS stat
GROUP BY key
ORDER BY count DESC, key;
```

key		count
line		883
query		207
pos		203
node		202
space		197
status		195
public		194
title		190
org		189
.....		

F.24.6. Compatibility

As of PostgreSQL 9.0, `hstore` uses a different internal representation than previous versions. This presents no obstacle for dump/restore upgrades since the text representation (used in the dump) is unchanged.

In the event of a binary upgrade, upward compatibility is maintained by having the new code recognize old-format data. This will entail a slight performance penalty when processing data that has not yet been modified by the new code. It is possible to force an upgrade of all values in a table column by doing an `UPDATE` statement as follows:

```
UPDATE tablename SET hstorecol = hstorecol || '';
```

Another way to do it is:

```
ALTER TABLE tablename ALTER hstorecol TYPE hstore USING hstorecol || '';
```

The `ALTER TABLE` method requires an `ACCESS EXCLUSIVE` lock on the table, but does not result in bloating the table with old row versions.

F.24.7. Transforms

Additional extensions are available that implement transforms for the `hstore` type for the languages PL/Perl and PL/Python. The extensions for PL/Perl are called `hstore_plperl` and `hstore_plperlu`, for trusted and untrusted PL/Perl. If you install these transforms and specify them when creating a function, `hstore` values are mapped to Perl hashes. The extension for PL/Python is called `hstore_plpython3u`. If you use it, `hstore` values are mapped to Python dictionaries.

Caution

It is strongly recommended that the transform extensions be installed in the same schema as `hstore`. Otherwise there are installation-time security hazards if a transform extension's schema contains objects defined by a hostile user.

F.24.8. Authors

Oleg Bartunov <oleg@sai.msu.su>, Moscow, Moscow University, Russia

Teodor Sigaev <teodor@sigaev.ru>, Moscow, Delta-Soft Ltd., Russia

Additional enhancements by Andrew Gierth <andrew@tao11.riddles.org.uk>, United Kingdom

F.25. Hunspell Dictionaries Modules

These modules provide Hunspell dictionaries for various languages. Upon installation of the module into database using `CREATE EXTENSION` command, text search dictionary and configuration objects in the public schema appear.

Table F.13. Modules

Language	Extension name	Dictionary name	Configuration name
American English	hunspell_en_us	english_hunspell	english_hunspell
Dutch	hunspell_nl_nl	dutch_hunspell	dutch_hunspell
French	hunspell_fr	french_hunspell	french_hunspell
Russian	hunspell_ru_ru	russian_hunspell	russian_hunspell

F.25.1. Examples

Text search objects will be created after installation of a dictionary module. We can test created configuration:

```
SELECT * FROM ts_debug('english_hunspell', 'abilities');
  alias | description | token | dictionaries |
  dictionary | lexemes
-----+-----+-----+-----+-----
+-----+-----+-----+-----+-----
  asciiword | Word, all ASCII | abilities | {english_hunspell,english_stem} |
  english_hunspell | {ability}
(1 row)
```

Or you can create your own text search configuration. For example, with the created dictionaries and with the `Snowball` dictionary you can create mixed russian-english configuration:

```
CREATE TEXT SEARCH CONFIGURATION russian_en (
  COPY = simple
);

ALTER TEXT SEARCH CONFIGURATION russian_en
  ALTER MAPPING FOR asciiword, asciihword, hword_asciipart
  WITH english_hunspell, english_stem;

ALTER TEXT SEARCH CONFIGURATION russian_en
  ALTER MAPPING FOR word, hword, hword_part
  WITH russian_hunspell, russian_stem;
```

You can create mixed dictionaries only for languages with different alphabets. If languages have similar alphabets then Postgres Pro can not decide which dictionary should be used.

A text search configuration which is created with a dictionary module is ready to use. For example, in this text you can search some words:

```
SELECT to_tsvector('english_hunspell', 'The blue whale is the largest animal');
      to_tsvector
-----
'animal':7 'blue':2 'large':6 'whale':3
(1 row)
```

Search query might looks like this:

```
SELECT to_tsvector('english_hunspell', 'The blue whale is the largest animal')
  @@ to_tsquery('english_hunspell', 'large & whale');
?column?
```

```
-----  
t  
(1 row)
```

With this configurations you can search a text using GIN or GIST indexes. For example, there is a table with GIN index:

```
CREATE TABLE table1 (t varchar);  
INSERT INTO table1 VALUES ('The blue whale is the largest animal');  
CREATE INDEX t_idx ON table1 USING GIN (to_tsvector('english_hunspell', "t"));
```

For this table you can execute the following query:

```
SELECT * FROM table1 where to_tsvector('english_hunspell', t)  
@@ to_tsquery('english_hunspell', 'blue & animal');  
t
```

```
-----  
The blue whale is the largest animal  
(1 row)
```

F.26. hypopg — support for hypothetical indexes

F.26.1. Description

hypopg is a Postgres Pro extension, adding support for *hypothetical indexes*.

A hypothetical, or virtual, index is an index that does not really exist, and therefore does not cost CPU, disk, or any resource to create. They are useful to find out whether specific indexes can increase the performance for problematic queries, since you can discover if Postgres Pro will use these indexes or not without having to spend resources to create them.

F.26.2. Installation

The hypopg extension is provided with Postgres Pro as a separate pre-built package `hypopg-ent-16` (for the detailed installation instructions, see [Chapter 16](#)). Once you have Postgres Pro installed, create the hypopg extension:

```
CREATE EXTENSION hypopg;
```

hypopg is now available. You can check easily if the extension is present using `psql`:

```
\dx
      List of installed extensions
  Name      | Version | Schema      | Description
  -----+-----+-----+-----
  hypopg    | 1.4.1   | public      | Hypothetical indexes for Postgres Pro
  plpgsql   | 1.0     | pg_catalog  | PL/pgSQL procedural language
(2 rows)
```

As you can see, hypopg is installed.

F.26.3. Functions

hypopg is useful if you want to check if some index would help one or multiple queries. Therefore, you should already know what are the queries you need to optimize, and ideas on which indexes you want to try.

Also, the hypothetical indexes that hypopg will create are not stored in any catalog, but in your connection private memory. Therefore, it won't bloat any table and won't impact any concurrent connection.

Moreover, since the hypothetical indexes don't really exist, hypopg makes sure they will only be using a simple `EXPLAIN` statement (without the `ANALYZE` option).

The following access methods are supported:

- `btree`
- `brin`
- `hash`
- `bloom` (requires the [bloom](#) extension to be installed)

Note

Using hypopg requires some knowledge on the [EXPLAIN](#) command.

F.26.3.1. Create a Hypothetical Index

```
hypopg_create_index()
```

For clarity, let's see how it works with a very simple test case:

```
CREATE TABLE hypo (id integer, val text) ;
INSERT INTO hypo SELECT i, 'line ' || i FROM generate_series(1, 100000) i ;
VACUUM ANALYZE hypo ;
```

This table doesn't have any index. Let's assume we want to check if an index would help a simple query. First, let's see how it behaves:

```
EXPLAIN SELECT val FROM hypo WHERE id = 1;
               QUERY PLAN
-----
Seq Scan on hypo  (cost=0.00..1791.00 rows=1 width=14)
  Filter: (id = 1)
(2 rows)
```

A plain sequential scan is used, since no index exists on the table. A simple btree index on the `id` column should help this query. Let's check with `hypopg`. The function `hypopg_create_index()` will accept any standard `CREATE INDEX` statement(s) (any other statement passed to this function will be ignored), and create a hypothetical index for each:

```
SELECT * FROM hypopg_create_index('CREATE INDEX ON hypo (id)') ;
 indexrelid |      indexname
-----+-----
      18284 | <18284>btree_hypo_id
(1 row)
```

The function returns two columns:

- the object identifier of the hypothetical index
- the generated hypothetical index name

We can run the `EXPLAIN` again to see if Postgres Pro would use this index:

```
EXPLAIN SELECT val FROM hypo WHERE id = 1;
               QUERY PLAN
-----
Index Scan using <18284>btree_hypo_id on hypo  (cost=0.04..8.06 rows=1 width=10)
  Index Cond: (id = 1)
(2 rows)
```

Yes, Postgres Pro would use such an index. Just to be sure, let's check that the hypothetical index won't be used to actually run the query:

```
EXPLAIN ANALYZE SELECT val FROM hypo WHERE id = 1;
               QUERY PLAN
-----
Seq Scan on hypo  (cost=0.00..1791.00 rows=1 width=10) (actual time=0.046..46.390
rows=1 loops=1)
  Filter: (id = 1)
  Rows Removed by Filter: 99999
Planning time: 0.160 ms
Execution time: 46.460 ms
(5 rows)
```

That's all you need to create hypothetical indexes and see if Postgres Pro would use such indexes.

F.26.3.2. Manipulate Hypothetical Indexes

The `hypopg_list_indexes` view lists all hypothetical indexes that have been created.

```
SELECT * FROM hypopg_list_indexes ;
 indexrelid |      index_name      | schema_name | table_name | am_name
-----+-----+-----+-----+-----
      18284 | <18284>btree_hypo_id | public      | hypo      | btree
```

(1 row)

hypopg()

hypopg() lists all hypothetical indexes that have been created with the same format as pg_index.

```
SELECT * FROM hypopg() ;
      indexname      | indexrelid | indrelid | innatts | indisunique | indkey |
indcollation | indclass | indoption | indexprs | indpred | amid
-----+-----+-----+-----+-----+-----+-----
<18284>btree_hypo_id |      13543 |      18122 |        1 | f          | 1      | 0
      | 1978      | <NULL>      | <NULL>      | <NULL>      | 403
(1 row)
```

hypopg_get_indexdef(oid)

hypopg_get_indexdef(oid) lists the CREATE INDEX statements that would recreate a stored hypothetical index.

```
SELECT index_name, hypopg_get_indexdef(indexrelid) FROM hypopg_list_indexes ;
      index_name      | hypopg_get_indexdef
-----+-----
<18284>btree_hypo_id | CREATE INDEX ON public.hypo USING btree (id)
(1 row)
```

hypopg_relation_size(oid)

hypopg_relation_size(oid) estimates how big a hypothetical index would be:

```
SELECT index_name, pg_size_pretty(hypopg_relation_size(indexrelid))
FROM hypopg_list_indexes ;
      index_name      | pg_size_pretty
-----+-----
<18284>btree_hypo_id | 2544 kB
(1 row)
```

hypopg_drop_index(oid)

hypopg_drop_index(oid) removes the given hypothetical index.

hypopg_reset()

hypopg_reset() removes all hypothetical indexes.

F.26.3.3. Hypothetically Hide Existing Indexes

hypopg_hide_index(oid)

You can hide both existing and hypothetical indexes hypothetically. If you want to test it as described in the documentation, you should first use hypopg_reset() to clear the effects of any other hypothetical indexes.

As a simple case, let's consider two indexes:

```
SELECT hypopg_reset();
CREATE INDEX ON hypo(id);
CREATE INDEX ON hypo(id, val);
EXPLAIN SELECT * FROM hypo WHERE id = 1;
               QUERY PLAN
-----
Index Only Scan using hypo_id_val_idx on hypo  (cost=0.29..8.30 rows=1 width=13)
Index Cond: (id = 1)
(2 rows)
```

The query plan is using the `hypo_id_val_idx` index now.

`hypopg_hide_index(oid)` allows you to hide an index in the `EXPLAIN` output by using its OID. It returns true if the index was successfully hidden, and false otherwise.

```
SELECT hypopg_hide_index('hypo_id_val_idx'::REGCLASS);
 hypopg_hide_index
```

```
t
(1 row)
```

```
EXPLAIN SELECT * FROM hypo WHERE id = 1;
               QUERY PLAN
```

```
Index Scan using hypo_id_idx on hypo  (cost=0.29..8.30 rows=1 width=13)
Index Cond: (id = 1)
(2 rows)
```

As an example, let's assume that the query plan is currently using the `hypo_id_val_idx` index. To continue testing, use the `hypopg_hide_index(oid)` function to hide another index.

```
SELECT hypopg_hide_index('hypo_id_idx'::REGCLASS);
 hypopg_hide_index
```

```
t
(1 row)
```

```
EXPLAIN SELECT * FROM hypo WHERE id = 1;
               QUERY PLAN
```

```
Seq Scan on hypo  (cost=0.00..180.00 rows=1 width=13)
Filter: (id = 1)
(2 rows)
```

`hypopg_unhide_index(oid)`

`hypopg_unhide_index(oid)` restores a previously hidden index in the `EXPLAIN` output by using its OID. It returns true if the index was successfully restored, and false otherwise.

```
SELECT hypopg_unhide_index('hypo_id_idx'::regclass);
 hypopg_unhide_index
```

```
t
(1 row)
```

```
EXPLAIN SELECT * FROM hypo WHERE id = 1;
               QUERY PLAN
```

```
Index Scan using hypo_id_idx on hypo  (cost=0.29..8.30 rows=1 width=13)
Index Cond: (id = 1)
(2 rows)
```

`hypopg_unhide_all_index(oid)`

`hypopg_unhide_all_index()` restores all hidden indexes and returns void.

`hypopg_hidden_indexes()`

`hypopg_hidden_indexes()` returns a list of OIDs for all hidden indexes.

```
SELECT * FROM hypopg_hidden_indexes();
 indexid
```

```
-----  
526604  
(1 rows)
```

The `hypopg_hidden_indexes` view returns a formatted list of all hidden indexes.

```
SELECT * FROM hypopg_hidden_indexes;  
 indexrelid |      index_name      | schema_name | table_name | am_name | is_hypo  
-----+-----+-----+-----+-----+-----  
      526604 | hypo_id_val_idx      | public      | hypo      | btree   | f  
(1 rows)
```

Note

Hypothetical indexes can be hidden as well.

```
SELECT hypopg_create_index('CREATE INDEX ON hypo(id)');  
hypopg_create_index  
-----  
(12659,<12659>btree_hypo_id)  
(1 row)
```

```
EXPLAIN SELECT * FROM hypo WHERE id = 1;  
QUERY PLAN  
-----  
Index Scan using "<12659>btree_hypo_id" on hypo  (cost=0.04..8.05 rows=1 width=13)  
Index Cond: (id = 1)  
(2 rows)
```

Now that the hypothetical index is being used, we can try hiding it to see the change:

```
SELECT hypopg_hide_index(12659);  
hypopg_hide_index  
-----  
t  
(1 row)
```

```
EXPLAIN SELECT * FROM hypo WHERE id = 1;  
QUERY PLAN  
-----  
Index Scan using hypo_id_idx on hypo  (cost=0.29..8.30 rows=1 width=13)  
Index Cond: (id = 1)  
(2 rows)
```

```
SELECT * FROM hypopg_hidden_indexes;  
 indexrelid |      index_name      | schema_name | table_name | am_name | is_hypo  
-----+-----+-----+-----+-----+-----  
      12659 | <12659>btree_hypo_id | public      | hypo      | btree   | t  
      526604 | hypo_id_val_idx      | public      | hypo      | btree   | f  
(2 rows)
```

Note

If a hypothetical index has been hidden, it will be automatically unhidden when it is deleted using `hypopg_drop_index(oid)` or `hypopg_reset()`.

```
SELECT hypopg_drop_index(12659);
```

```
SELECT * FROM hypopg_hidden_indexes;
 indexrelid |      index_name      | schema_name | table_name | am_name | is_hypo
-----+-----+-----+-----+-----+-----
      526604 | hypo_id_val_idx      | public      | hypo      | btree   | f
(2 rows)
```

F.26.4. GUC Parameters

The following configuration parameters (GUCs) are available, and can be changed interactively:

`hypopg.enabled`

Defaults to `on`. Use this parameter to globally enable or disable `hypopg`. When `hypopg` is disabled, no hypothetical index will be used, but the defined hypothetical indexes won't be removed.

`hypopg.use_real_oids`

Defaults to `off`. By default, `hypopg` won't use "real" object identifiers, but instead borrow ones from the `~ 14000 / 16384` (respectively the lowest unused OID less than `FirstNormalObjectId` and `FirstNormalObjectId`) range, which are reserved by Postgres Pro for future usage in future releases. This doesn't cause any problem, as the free range is dynamically computed the first time a connection uses `hypopg`, and has the advantage to work on a standby server. But the drawback is that you can't have more than approximately 2500 hypothetical indexes at the same time, and creating a new hypothetical index will become very slow once more than the maximum number of objects has been created until `hypopg_reset()` is called.

If those drawbacks are problematic, you can enable this parameter. `hypopg` will then ask for a real object identifier, which will need to obtain more locks and won't work on a standby, but will allow using the full range of object identifiers.

Note that switching this parameter doesn't require resetting the entries, both can coexist at the same time.

F.27. intagg — integer aggregator and enumerator

The `intagg` module provides an integer aggregator and an enumerator. `intagg` is now obsolete, because there are built-in functions that provide a superset of its capabilities. However, the module is still provided as a compatibility wrapper around the built-in functions.

F.27.1. Functions

The aggregator is an aggregate function `int_array_aggregate(integer)` that produces an integer array containing exactly the integers it is fed. This is a wrapper around `array_agg`, which does the same thing for any array type.

The enumerator is a function `int_array_enum(integer[])` that returns `setof integer`. It is essentially the reverse operation of the aggregator: given an array of integers, expand it into a set of rows. This is a wrapper around `unnest`, which does the same thing for any array type.

F.27.2. Sample Uses

Many database systems have the notion of a one to many table. Such a table usually sits between two indexed tables, for example:

```
CREATE TABLE left (id INT PRIMARY KEY, ...);
CREATE TABLE right (id INT PRIMARY KEY, ...);
CREATE TABLE one_to_many(left INT REFERENCES left, right INT REFERENCES right);
```

It is typically used like this:

```
SELECT right.* from right JOIN one_to_many ON (right.id = one_to_many.right)
WHERE one_to_many.left = item;
```

This will return all the items in the right hand table for an entry in the left hand table. This is a very common construct in SQL.

Now, this methodology can be cumbersome with a very large number of entries in the `one_to_many` table. Often, a join like this would result in an index scan and a fetch for each right hand entry in the table for a particular left hand entry. If you have a very dynamic system, there is not much you can do. However, if you have some data which is fairly static, you can create a summary table with the aggregator.

```
CREATE TABLE summary AS
SELECT left, int_array_aggregate(right) AS right
FROM one_to_many
GROUP BY left;
```

This will create a table with one row per left item, and an array of right items. Now this is pretty useless without some way of using the array; that's why there is an array enumerator. You can do

```
SELECT left, int_array_enum(right) FROM summary WHERE left = item;
```

The above query using `int_array_enum` produces the same results as

```
SELECT left, right FROM one_to_many WHERE left = item;
```

The difference is that the query against the summary table has to get only one row from the table, whereas the direct query against `one_to_many` must index scan and fetch a row for each entry.

On one system, an `EXPLAIN` showed a query with a cost of 8488 was reduced to a cost of 329. The original query was a join involving the `one_to_many` table, which was replaced by:

```
SELECT right, count(right) FROM
( SELECT left, int_array_enum(right) AS right
  FROM summary JOIN (SELECT left FROM left_table WHERE left = item) AS lefts
    ON (summary.left = lefts.left)
) AS list
GROUP BY right
```

Additional Supplied Modules
and Extensions Shipped in
postgrespro-std-16-contrib

ORDER BY count DESC;

F.28. intarray — manipulate arrays of integers

The `intarray` module provides a number of useful functions and operators for manipulating null-free arrays of integers. There is also support for indexed searches using some of the operators.

All of these operations will throw an error if a supplied array contains any `NULL` elements.

Many of these operations are only sensible for one-dimensional arrays. Although they will accept input arrays of more dimensions, the data is treated as though it were a linear array in storage order.

This module is considered “trusted”, that is, it can be installed by non-superusers who have `CREATE` privilege on the current database.

F.28.1. intarray Functions and Operators

The functions provided by the `intarray` module are shown in [Table F.14](#), the operators in [Table F.15](#).

Table F.14. intarray Functions

Function Description Example(s)
<code>icount (integer[]) → integer</code> Returns the number of elements in the array. <code>icount ('{1,2,3}'::integer[]) → 3</code>
<code>sort (integer[], dir text) → integer[]</code> Sorts the array in either ascending or descending order. <i>dir</i> must be <code>asc</code> or <code>desc</code> . <code>sort ('{1,3,2}'::integer[], 'desc') → {3,2,1}</code>
<code>sort (integer[]) → integer[]</code> <code>sort_asc (integer[]) → integer[]</code> Sorts in ascending order. <code>sort (array[11,77,44]) → {11,44,77}</code>
<code>sort_desc (integer[]) → integer[]</code> Sorts in descending order. <code>sort_desc (array[11,77,44]) → {77,44,11}</code>
<code>uniq (integer[]) → integer[]</code> Removes adjacent duplicates. Often used with <code>sort</code> to remove all duplicates. <code>uniq ('{1,2,2,3,1,1}'::integer[]) → {1,2,3,1}</code> <code>uniq (sort ('{1,2,3,2,1}'::integer[])) → {1,2,3}</code>
<code>idx (integer[], item integer) → integer</code> Returns index of the first array element matching <i>item</i> , or 0 if no match. <code>idx (array[11,22,33,22,11], 22) → 2</code>
<code>subarray (integer[], start integer, len integer) → integer[]</code> Extracts the portion of the array starting at position <i>start</i> , with <i>len</i> elements. <code>subarray ('{1,2,3,2,1}'::integer[], 2, 3) → {2,3,2}</code>
<code>subarray (integer[], start integer) → integer[]</code> Extracts the portion of the array starting at position <i>start</i> . <code>subarray ('{1,2,3,2,1}'::integer[], 2) → {2,3,2,1}</code>
<code>intset (integer) → integer[]</code> Makes a single-element array. <code>intset (42) → {42}</code>

Table F.15. intarray Operators

Operator	Description
<code>integer[] && integer[] → boolean</code>	Do arrays overlap (have at least one element in common)?
<code>integer[] @> integer[] → boolean</code>	Does left array contain right array?
<code>integer[] <@ integer[] → boolean</code>	Is left array contained in right array?
<code># integer[] → integer</code>	Returns the number of elements in the array.
<code>integer[] # integer → integer</code>	Returns index of the first array element matching the right argument, or 0 if no match. (Same as <code>idx</code> function.)
<code>integer[] + integer → integer[]</code>	Adds element to end of array.
<code>integer[] + integer[] → integer[]</code>	Concatenates the arrays.
<code>integer[] - integer → integer[]</code>	Removes entries matching the right argument from the array.
<code>integer[] - integer[] → integer[]</code>	Removes elements of the right array from the left array.
<code>integer[] integer → integer[]</code>	Computes the union of the arguments.
<code>integer[] integer[] → integer[]</code>	Computes the union of the arguments.
<code>integer[] & integer[] → integer[]</code>	Computes the intersection of the arguments.
<code>integer[] @@ query_int → boolean</code>	Does array satisfy query? (see below)
<code>query_int ~~ integer[] → boolean</code>	Does array satisfy query? (commutator of @@)

The operators `&&`, `@>` and `<@` are equivalent to Postgres Pro's built-in operators of the same names, except that they work only on integer arrays that do not contain nulls, while the built-in operators work for any array type. This restriction makes them faster than the built-in operators in many cases.

The `@@` and `~~` operators test whether an array satisfies a *query*, which is expressed as a value of a specialized data type `query_int`. A *query* consists of integer values that are checked against the elements of the array, possibly combined using the operators `&` (AND), `|` (OR), and `!` (NOT). Parentheses can be used as needed. For example, the query `1 & (2 | 3)` matches arrays that contain 1 and also contain either 2 or 3.

F.28.2. Index Support

`intarray` provides index support for the `&&`, `@>`, and `@@` operators, as well as regular array equality.

Two parameterized GiST index operator classes are provided: `gist__int_ops` (used by default) is suitable for small- to medium-size data sets, while `gist__intbig_ops` uses a larger signature and is more

suitable for indexing large data sets (i.e., columns containing a large number of distinct array values). The implementation uses an RD-tree data structure with built-in lossy compression.

`gist__int_ops` approximates an integer set as an array of integer ranges. Its optional integer parameter `numranges` determines the maximum number of ranges in one index key. The default value of `numranges` is 100. Valid values are between 1 and 253. Using larger arrays as GiST index keys leads to a more precise search (scanning a smaller fraction of the index and fewer heap pages), at the cost of a larger index.

`gist__intbig_ops` approximates an integer set as a bitmap signature. Its optional integer parameter `siglen` determines the signature length in bytes. The default signature length is 16 bytes. Valid values of signature length are between 1 and 2024 bytes. Longer signatures lead to a more precise search (scanning a smaller fraction of the index and fewer heap pages), at the cost of a larger index.

There is also a non-default GIN operator class `gin__int_ops`, which supports these operators as well as `<@`.

The choice between GiST and GIN indexing depends on the relative performance characteristics of GiST and GIN, which are discussed elsewhere.

F.28.3. Example

```
-- a message can be in one or more "sections"
CREATE TABLE message (mid INT PRIMARY KEY, sections INT[], ...);

-- create specialized index with signature length of 32 bytes
CREATE INDEX message_rdtree_idx ON message USING GIST (sections gist__intbig_ops
(siglen = 32));

-- select messages in section 1 OR 2 - OVERLAP operator
SELECT message.mid FROM message WHERE message.sections && '{1,2}';

-- select messages in sections 1 AND 2 - CONTAINS operator
SELECT message.mid FROM message WHERE message.sections @> '{1,2}';

-- the same, using QUERY operator
SELECT message.mid FROM message WHERE message.sections @@ '1&2'::query_int;
```

F.28.4. Authors

All work was done by Teodor Sigaev (<teodor@sigaev.ru>) and Oleg Bartunov (<oleg@sai.msu.su>). See <http://www.sai.msu.su/~megera/postgres/gist/> for additional information. Andrey Oktyabrski did a great work on adding new functions and operations.

F.29. isn — data types for international standard numbers (ISBN, EAN, UPC, etc.)

The `isn` module provides data types for the following international product numbering standards: EAN13, UPC, ISBN (books), ISMN (music), and ISSN (serials). Numbers are validated on input according to a hard-coded list of prefixes; this list of prefixes is also used to hyphenate numbers on output. Since new prefixes are assigned from time to time, the list of prefixes may be out of date. It is hoped that a future version of this module will obtain the prefix list from one or more tables that can be easily updated by users as needed; however, at present, the list can only be updated by modifying the source code and recompiling. Alternatively, prefix validation and hyphenation support may be dropped from a future version of this module.

This module is considered “trusted”, that is, it can be installed by non-superusers who have `CREATE` privilege on the current database.

F.29.1. Data Types

Table F.16 shows the data types provided by the `isn` module.

Table F.16. `isn` Data Types

Data Type	Description
EAN13	European Article Numbers, always displayed in the EAN13 display format
ISBN13	International Standard Book Numbers to be displayed in the new EAN13 display format
ISMN13	International Standard Music Numbers to be displayed in the new EAN13 display format
ISSN13	International Standard Serial Numbers to be displayed in the new EAN13 display format
ISBN	International Standard Book Numbers to be displayed in the old short display format
ISMN	International Standard Music Numbers to be displayed in the old short display format
ISSN	International Standard Serial Numbers to be displayed in the old short display format
UPC	Universal Product Codes

Some notes:

1. ISBN13, ISMN13, ISSN13 numbers are all EAN13 numbers.
2. EAN13 numbers aren't always ISBN13, ISMN13 or ISSN13 (some are).
3. Some ISBN13 numbers can be displayed as ISBN.
4. Some ISMN13 numbers can be displayed as ISMN.
5. Some ISSN13 numbers can be displayed as ISSN.
6. UPC numbers are a subset of the EAN13 numbers (they are basically EAN13 without the first 0 digit).
7. All UPC, ISBN, ISMN and ISSN numbers can be represented as EAN13 numbers.

Internally, all these types use the same representation (a 64-bit integer), and all are interchangeable. Multiple types are provided to control display formatting and to permit tighter validity checking of input that is supposed to denote one particular type of number.

The `ISBN`, `ISMN`, and `ISSN` types will display the short version of the number (ISxN 10) whenever it's possible, and will show ISxN 13 format for numbers that do not fit in the short version. The `EAN13`, `ISBN13`, `ISMN13` and `ISSN13` types will always display the long version of the ISxN (EAN13).

F.29.2. Casts

The `isn` module provides the following pairs of type casts:

- `ISBN13 <=> EAN13`
- `ISMN13 <=> EAN13`
- `ISSN13 <=> EAN13`
- `ISBN <=> EAN13`
- `ISMN <=> EAN13`
- `ISSN <=> EAN13`
- `UPC <=> EAN13`
- `ISBN <=> ISBN13`
- `ISMN <=> ISMN13`
- `ISSN <=> ISSN13`

When casting from `EAN13` to another type, there is a run-time check that the value is within the domain of the other type, and an error is thrown if not. The other casts are simply relabelings that will always succeed.

F.29.3. Functions and Operators

The `isn` module provides the standard comparison operators, plus B-tree and hash indexing support for all these data types. In addition there are several specialized functions; shown in [Table F.17](#). In this table, `isn` means any one of the module's data types.

Table F.17. `isn` Functions

Function	Description
<code>isn_weak (boolean) → boolean</code>	Sets the weak input mode, and returns new setting.
<code>isn_weak () → boolean</code>	Returns the current status of the weak mode.
<code>make_valid (isn) → isn</code>	Validates an invalid number (clears the invalid flag).
<code>is_valid (isn) → boolean</code>	Checks for the presence of the invalid flag.

Weak mode is used to be able to insert invalid data into a table. Invalid means the check digit is wrong, not that there are missing numbers.

Why would you want to use the weak mode? Well, it could be that you have a huge collection of ISBN numbers, and that there are so many of them that for weird reasons some have the wrong check digit (perhaps the numbers were scanned from a printed list and the OCR got the numbers wrong, perhaps the numbers were manually captured... who knows). Anyway, the point is you might want to clean the mess up, but you still want to be able to have all the numbers in your database and maybe use an external tool to locate the invalid numbers in the database so you can verify the information and validate it more easily; so for example you'd want to select all the invalid numbers in the table.

When you insert invalid numbers in a table using the weak mode, the number will be inserted with the corrected check digit, but it will be displayed with an exclamation mark (!) at the end, for example 0-11-000322-5!. This invalid marker can be checked with the `is_valid` function and cleared with the `make_valid` function.

You can also force the insertion of invalid numbers even when not in the weak mode, by appending the `!` character at the end of the number.

Another special feature is that during input, you can write `?` in place of the check digit, and the correct check digit will be inserted automatically.

F.29.4. Examples

```
--Using the types directly:
SELECT isbn('978-0-393-04002-9');
SELECT isbn13('0901690546');
SELECT issn('1436-4522');

--Casting types:
-- note that you can only cast from ean13 to another type when the
-- number would be valid in the realm of the target type;
-- thus, the following will NOT work: select isbn(ean13('0220356483481'));
-- but these will:
SELECT upc(ean13('0220356483481'));
SELECT ean13(upc('220356483481'));

--Create a table with a single column to hold ISBN numbers:
CREATE TABLE test (id isbn);
INSERT INTO test VALUES('9780393040029');

--Automatically calculate check digits (observe the '?'):
INSERT INTO test VALUES('220500896?');
INSERT INTO test VALUES('978055215372?');

SELECT issn('3251231?');
SELECT ismn('979047213542?');

--Using the weak mode:
SELECT isn_weak(true);
INSERT INTO test VALUES('978-0-11-000533-4');
INSERT INTO test VALUES('9780141219307');
INSERT INTO test VALUES('2-205-00876-X');
SELECT isn_weak(false);

SELECT id FROM test WHERE NOT is_valid(id);
UPDATE test SET id = make_valid(id) WHERE id = '2-205-00876-X!';

SELECT * FROM test;

SELECT isbn13(id) FROM test;
```

F.29.5. Bibliography

The information to implement this module was collected from several sites, including:

- <https://www.isbn-international.org/>
- <https://www.issn.org/>
- <https://www.ismn-international.org/>

- <https://www.wikipedia.org/>

The prefixes used for hyphenation were also compiled from:

- <https://www.gs1.org/standards/id-keys>
- https://en.wikipedia.org/wiki/List_of_ISBN_identifier_groups
- <https://www.isbn-international.org/content/isbn-users-manual/29>
- https://en.wikipedia.org/wiki/International_Standard_Music_Number
- <https://www.ismn-international.org/ranges/tools>

Care was taken during the creation of the algorithms and they were meticulously verified against the suggested algorithms in the official ISBN, ISMN, ISSN User Manuals.

F.29.6. Author

Germán Méndez Bravo (Kronuz), 2004–2006

This module was inspired by Garrett A. Wollman's `isbn_issn` code.

F.30. jquery — a language to query jsonb data type

jQuery is a language to query jsonb data type. Its primary goal is to provide an additional functionality for jsonb, such as a simple and effective way for search in nested objects and arrays, as well as additional comparison operators with index support.

jQuery is implemented by means of a jquery data type (similar to tsquery) and the @@ match operator for jsonb.

F.30.1. Installation

Postgres Pro Standard distribution includes jquery as a contrib module. Once you complete Postgres Pro Standard installation, create the jquery extension, as follows:

```
CREATE EXTENSION jquery;
```

F.30.2. JSON query language

jQuery extension contains jquery datatype which represents whole JSON query as a single value (like tsquery does for fulltext search). The query is an expression on JSON-document values.

Simple expression is specified as *path binary_operator value* or *path unary_operator*. See the following examples.

- `x = "abc"` - value of key "x" is equal to "abc";
- `$ @> [4, 5, "zzz"]` - the JSON document is an array containing values 4, 5 and "zzz";
- `"abc xyz" >= 10` - value of key "abc xyz" is greater than or equal to 10;
- `volume IS NUMERIC` - type of key "volume" is numeric.
- `$ = true` - the whole JSON document is just a true.
- `similar_ids.@# > 5` - similar_ids is an array or object of length greater than 5;
- `similar_product_ids.# = "0684824396"` - array similar_product_ids contains string "0684824396".
- `*.color = "red"` - there is object somewhere which key "color" has value "red".
- `foo = *` - key "foo" exists in object.

Path selects set of JSON values to be checked using given operators. In the simplest case, path is just a key name. In general, path is key names and placeholders combined by dot signs. Path can use the following placeholders:

- `#` - any index of array;
- `#N` - Nth index of array;
- `%` - any key of object;
- `*` - any sequence of array indexes and object keys;
- `@#` - length of array or object, could be only used as last component of path;
- `$` - the whole JSON document as single value, could be only the whole path.

Expression is true when operator is true against at least one value selected by path.

Key names could be given either with or without double quotes. Key names without double quotes shouldn't contain spaces, start with number, or concur with jquery keyword.

The supported binary operators are:

- Equality operator: `=`;
- Numeric comparison operators: `>`, `>=`, `<`, `<=`;
- Search in the list of scalar values using `IN` operator;
- Array comparison operators: `&&` (overlap), `@>` (contains), `<@` (contained in).
- Filtering operator: `~~`. Taking jsonb data as the left operand and a jquery expression as the right operand, this operator checks that jsonb data contains any entries that satisfy the condition provided in a jquery expression and returns an array of such entries, if any.

The supported unary operators are:

- Check for existence operator: `= *`;
- Check for type operators: `IS ARRAY`, `IS NUMERIC`, `IS OBJECT`, `IS STRING` and `IS BOOLEAN`.

Expressions could be complex. Complex expression is a set of expressions combined by logical operators (`AND`, `OR`, `NOT`) and grouped using parentheses.

Examples of complex expressions are given below.

- `a = 1 AND (b = 2 OR c = 3) AND NOT d = 1`
- `x.% = true OR x.# = true`

Prefix expressions are expressions given in the form `path (subexpression)`. In this case `path` selects JSON values to be checked using given subexpression. Check results are aggregated in the same way as in simple expressions.

- `#(a = 1 AND b = 2)` - an array contains an element where the `a` key is 2 and the `b` key is 2
- `%( $ >= 10 AND $ <= 20 )` - an object contains a key with a value between 10 and 20

Path also could contain the following special placeholders with "every" semantics:

- `#:` - every index of array;
- `%:` - every key of object;
- `*` - every sequence of array indexes and object keys.

Consider the following example.

```
%.#:( $ >= 0 AND $ <= 1 )
```

This example could be read as follows: there is at least one key for which the value is an array of numerics between 0 and 1.

We can rewrite this example in the following form with extra parentheses.

```
%(#:( $ >= 0 AND $ <= 1 ) )
```

The first placeholder `%` checks that expression in parentheses is true for at least one value in object. The second placeholder `#:` checks that the value is an array and all its elements satisfy expressions in parentheses.

We can rewrite this example without `#:` placeholder as follows.

```
%(NOT #(NOT ( $ >= 0 AND $ <= 1 ) ) AND $ IS ARRAY)
```

In this example we transform assertion that every element of array satisfies some condition to assertion that there is no one element which doesn't satisfy the same condition.

Some examples of using paths are given below.

- `numbers.#: IS NUMERIC` - every element of "numbers" array is numeric.
- `*:( $ IS OBJECT OR $ IS BOOLEAN )` - JSON is a structure of nested objects with booleans as leaf values.
- `#.:%:( $ >= 0 AND $ <= 1 )` - each element of array is object containing only numeric values between 0 and 1.
- `documents.#:.% = *` - "documents" is an array of objects containing at least one key.
- `%.#:( $ IS STRING )` - JSON object contains at least one array of strings.
- `%.% = true` - at least one array element is an object that contains at least one "true" value.

Usage of path operators and parentheses needs some explanation. When same path operators are used multiple times they may refer to different values while you can refer to the same value multiple times by using parentheses and `$` operator. See the following examples.

- `# < 10 AND # > 20` - there is an element less than 10 and another element greater than 20.

- `#$ < 10 AND $ > 20` - there is an element that is both less than 10 and greater than 20 (impossible).
- `#$ >= 10 AND $ <= 20` - there is an element between 10 and 20.
- `# >= 10 AND # <= 20` - there is an element greater than or equal to 10 and another element less than or equal to 20. The query can be satisfied by an array with no elements between 10 and 20, for instance `[0,30]`.

Same rules apply when you search inside objects and branchy structures.

Type checking operators and "every" placeholders are useful for document schema validation. JQuery matching operator `@@` is immutable and can be used in CHECK constraint. See the following example.

```
CREATE TABLE js (  
    id serial,  
    data jsonb,  
    CHECK (data @@ '  
        name IS STRING AND  
        similar_ids.#: IS NUMERIC AND  
        points.#:(x IS NUMERIC AND y IS NUMERIC) '::jsquery));
```

In this example check constraint validates that in "data" jsonb column: value of "name" key is string, value of "similar_ids" key is array of numerics, value of "points" key is array of objects which contain numeric values in "x" and "y" keys.

See our [pgconf.eu presentation](https://pgconf.eu/presentation) for more examples.

F.30.3. GIN indexes

JQuery extension contains two operator classes (opclasses) for GIN which provide different kinds of query optimization.

- `jsonb_path_value_ops`
- `jsonb_value_path_ops`

In each of two GIN opclasses jsonb documents are decomposed into entries. Each entry is associated with a particular value and its path. Difference between opclasses is in the entry representation, comparison, and usage for search optimization.

For example, jsonb document `{"a": [{ "b": "xyz", "c": true }, 10], "d": { "e": [7, false] }}` would be decomposed into the following entries:

- `"a".#."b"."xyz"`
- `"a".#."c".true`
- `"a".#.10`
- `"d"."e".#.7`
- `"d"."e".#.false`

Since JQuery doesn't support search in a particular array index, we consider all array elements to be equivalent. Thus, each array element is marked with the same # sign in the path.

Major problem in the entries representation is its size. In the given example key "a" is presented three times. In the large branchy documents with long keys size of naive entries representation becomes unreasonable. Both opclasses address this issue but in a slightly different way.

F.30.3.1. jsonb_path_value_ops

`jsonb_path_value_ops` represents entry as pair of path hash and value. The following pseudocode illustrates it.

```
(hash(path_item_1.path_item_2. ... .path_item_n); value)
```

In comparison of entries path hash is the higher part of entry and value is its lower part. This determines the features of this opclass. Since path is hashed and it is higher part of entry we need to know the full

path to the value in order to use it for search. However, once path is specified we can use both exact and range searches very efficiently.

F.30.3.2. jsonb_value_path_ops

jsonb_value_path_ops represents entry as pair of value and bloom filter of path.

```
(value; bloom(path_item_1) | bloom(path_item_2) | ... | bloom(path_item_n))
```

In comparison of entries value is the higher part of entry and bloom filter of path is its lower part. This determines the features of this opclass. Since value is the higher part of entry we can perform only exact value search efficiently. Range value search is possible as well but we would have to filter all the different paths where matching values occur. Bloom filter over path items allows index usage for conditions containing % and * in their paths.

F.30.3.3. Query optimization

JsQuery opclasses perform complex query optimization. Thus it's valuable for developer or administrator to see the result of such optimization. Unfortunately, opclasses aren't allowed to do any custom output to the EXPLAIN. That's why JsQuery provides the following functions which allows to see how particular opclass optimizes given query.

- gin_debug_query_path_value(jsquery) - for jsonb_path_value_ops
- gin_debug_query_value_path(jsquery) - for jsonb_value_path_ops

Result of these functions is a textual representation of query tree which leaves are GIN search entries. The following examples show different results of query optimization by different opclasses.

```
# SELECT gin_debug_query_path_value('x = 1 AND (*.y = 1 OR y = 2)');
gin_debug_query_path_value
-----
x = 1 , entry 0          +

# SELECT gin_debug_query_value_path('x = 1 AND (*.y = 1 OR y = 2)');
gin_debug_query_value_path
-----
AND                      +
  x = 1 , entry 0        +
  OR                     +
    *.y = 1 , entry 1    +
    y = 2 , entry 2      +
```

Unfortunately, jsonb has no statistics yet. That's why JsQuery optimizer has to do imperative decision while selecting conditions to be evaluated using index. This decision is made by assumption that some condition types are less selective than others. Optimizer divides conditions into the following selectivity class (listed by descending of selectivity).

1. Equality (x = c)
2. Range (c1 < x < c2)
3. Inequality (x > c)
4. Is (x is type)
5. Any (x = *)

Optimizer evades index evaluation of less selective conditions when possible. For example, in the `x = 1 AND y > 0` query `x = 1` is assumed to be more selective than `y > 0`. That's why index isn't used for evaluation of `y > 0`.

```
# SELECT gin_debug_query_path_value('x = 1 AND y > 0');
gin_debug_query_path_value
-----
x = 1 , entry 0          +
```

With lack of statistics decisions made by optimizer can be inaccurate. That's why JQuery supports hints. Comments `/*-- index */` and `/*-- noindex */` placed in the conditions force optimizer to use and not to use index correspondingly.

```
SELECT gin_debug_query_path_value('x = 1 AND y /*-- index */ > 0');
gin_debug_query_path_value
-----
AND                               +
  x = 1 , entry 0                 +
  y > 0 , entry 1                 +

SELECT gin_debug_query_path_value('x /*-- noindex */ = 1 AND y > 0');
gin_debug_query_path_value
-----
y > 0 , entry 0                 +
```

F.31. lo — manage large objects

The `lo` module provides support for managing Large Objects (also called LOs or BLOBs). This includes a data type `lo` and a trigger `lo_manage`.

This module is considered “trusted”, that is, it can be installed by non-superusers who have `CREATE` privilege on the current database.

F.31.1. Rationale

One of the problems with the JDBC driver (and this affects the ODBC driver also), is that the specification assumes that references to BLOBs (Binary Large Objects) are stored within a table, and if that entry is changed, the associated BLOB is deleted from the database.

As Postgres Pro stands, this doesn't occur. Large objects are treated as objects in their own right; a table entry can reference a large object by OID, but there can be multiple table entries referencing the same large object OID, so the system doesn't delete the large object just because you change or remove one such entry.

Now this is fine for Postgres Pro-specific applications, but standard code using JDBC or ODBC won't delete the objects, resulting in orphan objects — objects that are not referenced by anything, and simply occupy disk space.

The `lo` module allows fixing this by attaching a trigger to tables that contain LO reference columns. The trigger essentially just does a `lo_unlink` whenever you delete or modify a value referencing a large object. When you use this trigger, you are assuming that there is only one database reference to any large object that is referenced in a trigger-controlled column!

The module also provides a data type `lo`, which is really just a [domain](#) over the `oid` type. This is useful for differentiating database columns that hold large object references from those that are OIDs of other things. You don't have to use the `lo` type to use the trigger, but it may be convenient to use it to keep track of which columns in your database represent large objects that you are managing with the trigger. It is also rumored that the ODBC driver gets confused if you don't use `lo` for BLOB columns.

F.31.2. How to Use It

Here's a simple example of usage:

```
CREATE TABLE image (title text, raster lo);

CREATE TRIGGER t_raster BEFORE UPDATE OR DELETE ON image
    FOR EACH ROW EXECUTE FUNCTION lo_manage(raster);
```

For each column that will contain unique references to large objects, create a `BEFORE UPDATE OR DELETE` trigger, and give the column name as the sole trigger argument. You can also restrict the trigger to only execute on updates to the column by using `BEFORE UPDATE OF column_name`. If you need multiple `lo` columns in the same table, create a separate trigger for each one, remembering to give a different name to each trigger on the same table.

F.31.3. Limitations

- Dropping a table will still orphan any objects it contains, as the trigger is not executed. You can avoid this by preceding the `DROP TABLE` with `DELETE FROM table`.

`TRUNCATE` has the same hazard.

If you already have, or suspect you have, orphaned large objects, see the [vacuumlo](#) module to help you clean them up. It's a good idea to run `vacuumlo` occasionally as a back-stop to the `lo_manage` trigger.

- Some frontends may create their own tables, and will not create the associated trigger(s). Also, users may not remember (or know) to create the triggers.

Peter Mount <[mailto:peter@retep.org.uk]>

F.32. ltree — hierarchical tree-like data type

This module implements a data type `ltree` for representing labels of data stored in a hierarchical tree-like structure. Extensive facilities for searching through label trees are provided.

This module is considered “trusted”, that is, it can be installed by non-superusers who have `CREATE` privilege on the current database.

F.32.1. Definitions

A *label* is a sequence of alphanumeric characters, underscores, and hyphens. Valid alphanumeric character ranges are dependent on the database locale. For example, in C locale, the characters `A-Za-z0-9_-` are allowed. Labels must be no more than 1000 characters long.

Examples: `42`, `Personal_Services`

A *label path* is a sequence of zero or more labels separated by dots, for example `L1.L2.L3`, representing a path from the root of a hierarchical tree to a particular node. The length of a label path cannot exceed 65535 labels.

Example: `Top.Countries.Europe.Russia`

The `ltree` module provides several data types:

- `ltree` stores a label path.
- `lquery` represents a regular-expression-like pattern for matching `ltree` values. A simple word matches that label within a path. A star symbol (`*`) matches zero or more labels. These can be joined with dots to form a pattern that must match the whole label path. For example:

<code>foo</code>	<i>Match the exact label path foo</i>
<code>*.foo.*</code>	<i>Match any label path containing the label foo</i>
<code>*.foo</code>	<i>Match any label path whose last label is foo</i>

Both star symbols and simple words can be quantified to restrict how many labels they can match:

<code>*{n}</code>	<i>Match exactly n labels</i>
<code>*{n,}</code>	<i>Match at least n labels</i>
<code>*{n,m}</code>	<i>Match at least n but not more than m labels</i>
<code>*{,m}</code>	<i>Match at most m labels – same as <code>*{0,m}</code></i>
<code>foo{n,m}</code>	<i>Match at least n but not more than m occurrences of foo</i>
<code>foo{,}</code>	<i>Match any number of occurrences of foo, including zero</i>

In the absence of any explicit quantifier, the default for a star symbol is to match any number of labels (that is, `{,}`) while the default for a non-star item is to match exactly once (that is, `{1}`).

There are several modifiers that can be put at the end of a non-star `lquery` item to make it match more than just the exact match:

<code>@</code>	<i>Match case-insensitively, for example <code>a@</code> matches <code>A</code></i>
<code>*</code>	<i>Match any label with this prefix, for example <code>foo*</code> matches <code>foobar</code></i>
<code>%</code>	<i>Match initial underscore-separated words</i>

The behavior of `%` is a bit complicated. It tries to match words rather than the entire label. For example `foo_bar%` matches `foo_bar_baz` but not `foo_barbaz`. If combined with `*`, prefix matching applies to each word separately, for example `foo_bar%*` matches `foo1_bar2_baz` but not `foo1_br2_baz`.

Also, you can write several possibly-modified non-star items separated with `|` (OR) to match any of those items, and you can put `!` (NOT) at the start of a non-star group to match any label that doesn't match any of the alternatives. A quantifier, if any, goes at the end of the group; it means

some number of matches for the group as a whole (that is, some number of labels matching or not matching any of the alternatives).

Here's an annotated example of `lquery`:

```
Top.*{0,2}.sport*@.!football|tennis{1,}.Russ*|Spain
a.  b.      c.      d.      e.
```

This query will match any label path that:

- a. begins with the label `Top`
 - b. and next has zero to two labels before
 - c. a label beginning with the case-insensitive prefix `sport`
 - d. then has one or more labels, none of which match `football` nor `tennis`
 - e. and then ends with a label beginning with `Russ` or exactly matching `Spain`.
- `ltxquery` represents a full-text-search-like pattern for matching `ltree` values. An `ltxquery` value contains words, possibly with the modifiers `@`, `*`, `%` at the end; the modifiers have the same meanings as in `lquery`. Words can be combined with `&` (AND), `|` (OR), `!` (NOT), and parentheses. The key difference from `lquery` is that `ltxquery` matches words without regard to their position in the label path.

Here's an example `ltxquery`:

```
Europe & Russia*@ & !Transportation
```

This will match paths that contain the label `Europe` and any label beginning with `Russia` (case-insensitive), but not paths containing the label `Transportation`. The location of these words within the path is not important. Also, when `%` is used, the word can be matched to any underscore-separated word within a label, regardless of position.

Note: `ltxquery` allows whitespace between symbols, but `ltree` and `lquery` do not.

F.32.2. Operators and Functions

Type `ltree` has the usual comparison operators `=`, `<>`, `<`, `>`, `<=`, `>=`. Comparison sorts in the order of a tree traversal, with the children of a node sorted by label text. In addition, the specialized operators shown in Table F.18 are available.

Table F.18. `ltree` Operators

Operator	Description
<code>ltree @> ltree → boolean</code> Is left argument an ancestor of right (or equal)?	
<code>ltree <@ ltree → boolean</code> Is left argument a descendant of right (or equal)?	
<code>ltree ~ lquery → boolean</code> <code>lquery ~ ltree → boolean</code> Does <code>ltree</code> match <code>lquery</code> ?	
<code>ltree ? lquery[] → boolean</code> <code>lquery[] ? ltree → boolean</code> Does <code>ltree</code> match any <code>lquery</code> in array?	
<code>ltree @ ltxquery → boolean</code> <code>ltxquery @ ltree → boolean</code> Does <code>ltree</code> match <code>ltxquery</code> ?	

Operator	Description
<code>ltree ltree → ltree</code> Concatenates <code>ltree</code> paths.	
<code>ltree text → ltree</code> <code>text ltree → ltree</code> Converts <code>text</code> to <code>ltree</code> and concatenates.	
<code>ltree[] @> ltree → boolean</code> <code>ltree <@ ltree[] → boolean</code> Does array contain an ancestor of <code>ltree</code> ?	
<code>ltree[] <@ ltree → boolean</code> <code>ltree @> ltree[] → boolean</code> Does array contain a descendant of <code>ltree</code> ?	
<code>ltree[] ~ lquery → boolean</code> <code>lquery ~ ltree[] → boolean</code> Does array contain any path matching <code>lquery</code> ?	
<code>ltree[] ? lquery[] → boolean</code> <code>lquery[] ? ltree[] → boolean</code> Does <code>ltree</code> array contain any path matching any <code>lquery</code> ?	
<code>ltree[] @ ltxtquery → boolean</code> <code>ltxtquery @ ltree[] → boolean</code> Does array contain any path matching <code>ltxtquery</code> ?	
<code>ltree[] ?@> ltree → ltree</code> Returns first array entry that is an ancestor of <code>ltree</code> , or <code>NULL</code> if none.	
<code>ltree[] ?<@ ltree → ltree</code> Returns first array entry that is a descendant of <code>ltree</code> , or <code>NULL</code> if none.	
<code>ltree[] ?~ lquery → ltree</code> Returns first array entry that matches <code>lquery</code> , or <code>NULL</code> if none.	
<code>ltree[] ?@ ltxtquery → ltree</code> Returns first array entry that matches <code>ltxtquery</code> , or <code>NULL</code> if none.	

The operators `<@`, `@>`, `@` and `~` have analogues `^<@`, `^@>`, `^@`, `^~`, which are the same except they do not use indexes. These are useful only for testing purposes.

The available functions are shown in [Table F.19](#).

Table F.19. `ltree` Functions

Function	Description	Example(s)
<code>subltree (ltree, start integer, end integer) → ltree</code> Returns subpath of <code>ltree</code> from position <code>start</code> to position <code>end-1</code> (counting from 0). <code>subltree('Top.Child1.Child2', 1, 2) → Child1</code>		
<code>subpath (ltree, offset integer, len integer) → ltree</code> Returns subpath of <code>ltree</code> starting at position <code>offset</code> , with length <code>len</code> . If <code>offset</code> is negative, subpath starts that far from the end of the path. If <code>len</code> is negative, leaves that many labels off the end of the path.		

Function	Description	Example(s)
		<code>subpath('Top.Child1.Child2', 0, 2) → Top.Child1</code>
	<code>subpath (ltree, offset integer) → ltree</code> Returns subpath of <code>ltree</code> starting at position <code>offset</code> , extending to end of path. If <code>offset</code> is negative, subpath starts that far from the end of the path.	<code>subpath('Top.Child1.Child2', 1) → Child1.Child2</code>
	<code>nlevel (ltree) → integer</code> Returns number of labels in path.	<code>nlevel('Top.Child1.Child2') → 3</code>
	<code>index (a ltree, b ltree) → integer</code> Returns position of first occurrence of <code>b</code> in <code>a</code> , or -1 if not found.	<code>index('0.1.2.3.5.4.5.6.8.5.6.8', '5.6') → 6</code>
	<code>index (a ltree, b ltree, offset integer) → integer</code> Returns position of first occurrence of <code>b</code> in <code>a</code> , or -1 if not found. The search starts at position <code>offset</code> ; negative <code>offset</code> means start <code>-offset</code> labels from the end of the path.	<code>index('0.1.2.3.5.4.5.6.8.5.6.8', '5.6', -4) → 9</code>
	<code>text2ltree (text) → ltree</code> Casts text to ltree.	
	<code>ltree2text (ltree) → text</code> Casts ltree to text.	
	<code>lca (ltree [, ltree [, ...]]) → ltree</code> Computes longest common ancestor of paths (up to 8 arguments are supported).	<code>lca('1.2.3', '1.2.3.4.5.6') → 1.2</code>
	<code>lca (ltree[]) → ltree</code> Computes longest common ancestor of paths in array.	<code>lca(array['1.2.3'::ltree, '1.2.3.4']) → 1.2</code>

F.32.3. Indexes

`ltree` supports several types of indexes that can speed up the indicated operators:

- B-tree index over `ltree`: `<, <=, =, >=, >`
- GiST index over `ltree` (`gist_ltree_ops` opclass): `<, <=, =, >=, >, @>, <@, @, ~, ?`

`gist_ltree_ops` GiST opclass approximates a set of path labels as a bitmap signature. Its optional integer parameter `siglen` determines the signature length in bytes. The default signature length is 8 bytes. The length must be a positive multiple of `int` alignment (4 bytes on most machines) up to 2024. Longer signatures lead to a more precise search (scanning a smaller fraction of the index and fewer heap pages), at the cost of a larger index.

Example of creating such an index with the default signature length of 8 bytes:

```
CREATE INDEX path_gist_idx ON test USING GIST (path);
```

Example of creating such an index with a signature length of 100 bytes:

```
CREATE INDEX path_gist_idx ON test USING GIST (path gist_ltree_ops(siglen=100));
```

- GiST index over `ltree[]` (`gist__ltree_ops` opclass): `ltree[] <@ ltree, ltree @> ltree[], @, ~, ?`

`gist__ltree_ops` GiST opclass works similarly to `gist_ltree_ops` and also takes signature length as a parameter. The default value of `siglen` in `gist__ltree_ops` is 28 bytes.

Example of creating such an index with the default signature length of 28 bytes:

```
CREATE INDEX path_gist_idx ON test USING GIST (array_path);
```

Example of creating such an index with a signature length of 100 bytes:

```
CREATE INDEX path_gist_idx ON test USING GIST (array_path
gist__ltree_ops(siglen=100));
```

Note: This index type is lossy.

F.32.4. Example

This example uses the following data (also available in file `contrib/ltree/ltreetest.sql` in the source distribution):

```
CREATE TABLE test (path ltree);
INSERT INTO test VALUES ('Top');
INSERT INTO test VALUES ('Top.Science');
INSERT INTO test VALUES ('Top.Science.Astronomy');
INSERT INTO test VALUES ('Top.Science.Astronomy.Astrophysics');
INSERT INTO test VALUES ('Top.Science.Astronomy.Cosmology');
INSERT INTO test VALUES ('Top.Hobbies');
INSERT INTO test VALUES ('Top.Hobbies.Amateurs_Astronomy');
INSERT INTO test VALUES ('Top.Collections');
INSERT INTO test VALUES ('Top.Collections.Pictures');
INSERT INTO test VALUES ('Top.Collections.Pictures.Astronomy');
INSERT INTO test VALUES ('Top.Collections.Pictures.Astronomy.Stars');
INSERT INTO test VALUES ('Top.Collections.Pictures.Astronomy.Galaxies');
INSERT INTO test VALUES ('Top.Collections.Pictures.Astronomy.Astronauts');
CREATE INDEX path_gist_idx ON test USING GIST (path);
CREATE INDEX path_idx ON test USING BTREE (path);
```

Now, we have a table `test` populated with data describing the hierarchy shown below:

```

              Top
            /  |  \
      Science Hobbies Collections
        /      |      \
    Astronomy Amateurs_Astronomy Pictures
      /  \                |
Astrophysics  Cosmology      Astronomy
                        /  |  \
                        Galaxies Stars Astronauts
```

We can do inheritance:

```
ltreetest=> SELECT path FROM test WHERE path <@ 'Top.Science';
           path
```

```
-----
Top.Science
Top.Science.Astronomy
Top.Science.Astronomy.Astrophysics
Top.Science.Astronomy.Cosmology
(4 rows)
```

Here are some examples of path matching:

```
ltreetest=> SELECT path FROM test WHERE path ~ '*.Astronomy.*';
```

path

```
-----
Top.Science.Astronomy
Top.Science.Astronomy.Astrophysics
Top.Science.Astronomy.Cosmology
Top.Collections.Pictures.Astronomy
Top.Collections.Pictures.Astronomy.Stars
Top.Collections.Pictures.Astronomy.Galaxies
Top.Collections.Pictures.Astronomy.Astronauts
(7 rows)
```

```
ltreetest=> SELECT path FROM test WHERE path ~ '.*!pictures@.Astronomy.*';
           path
```

```
-----
Top.Science.Astronomy
Top.Science.Astronomy.Astrophysics
Top.Science.Astronomy.Cosmology
(3 rows)
```

Here are some examples of full text search:

```
ltreetest=> SELECT path FROM test WHERE path @ 'Astro*% & !pictures@';
           path
```

```
-----
Top.Science.Astronomy
Top.Science.Astronomy.Astrophysics
Top.Science.Astronomy.Cosmology
Top.Hobbies.Amateurs_Astronomy
(4 rows)
```

```
ltreetest=> SELECT path FROM test WHERE path @ 'Astro* & !pictures@';
           path
```

```
-----
Top.Science.Astronomy
Top.Science.Astronomy.Astrophysics
Top.Science.Astronomy.Cosmology
(3 rows)
```

Path construction using functions:

```
ltreetest=> SELECT subpath(path,0,2) || 'Space' || subpath(path,2) FROM test WHERE path <@
           'Top.Science.Astronomy';
           ?column?
```

```
-----
Top.Science.Space.Astronomy
Top.Science.Space.Astronomy.Astrophysics
Top.Science.Space.Astronomy.Cosmology
(3 rows)
```

We could simplify this by creating an SQL function that inserts a label at a specified position in a path:

```
CREATE FUNCTION ins_label(ltree, int, text) RETURNS ltree
AS 'select subpath($1,0,$2) || $3 || subpath($1,$2);'
LANGUAGE SQL IMMUTABLE;
```

```
ltreetest=> SELECT ins_label(path,2,'Space') FROM test WHERE path <@
           'Top.Science.Astronomy';
           ins_label
```

```
-----
Top.Science.Space.Astronomy
```

```
Top.Science.Space.Astronomy.Astrophysics
Top.Science.Space.Astronomy.Cosmology
(3 rows)
```

F.32.5. Transforms

The `ltree_plpython3u` extension implements transforms for the `ltree` type for PL/Python. If installed and specified when creating a function, `ltree` values are mapped to Python lists. (The reverse is currently not supported, however.)

Caution

It is strongly recommended that the transform extension be installed in the same schema as `ltree`. Otherwise there are installation-time security hazards if a transform extension's schema contains objects defined by a hostile user.

F.32.6. Authors

All work was done by Teodor Sigaev (<teodor@stack.net>) and Oleg Bartunov (<oleg@sai.msu.su>). See <http://www.sai.msu.su/~megera/postgres/gist/> for additional information. Authors would like to thank Eugeny Rodichev for helpful discussions. Comments and bug reports are welcome.

F.33. mchar — additional data types for compatibility with Microsoft SQL Server

The `mchar` module provides additional data types for compatibility with Microsoft SQL Server (MS SQL).

F.33.1. Overview

This module has been designed to improve 1C Enterprise support, most popular Russian CRM and ERP system.

It implements types `MCHAR` and `MVARCHAR`, which are bug-to-bug compatible with MS SQL `CHAR` and `VARCHAR` respectively. Additionally, these types use the ICU library for comparison and case conversion, so their behavior is identical across different operating systems.

Postgres Pro also includes `citext` extension which provides types similar to `MCHAR`. But this extension doesn't emulate MS-SQL behavior concerning end-of-value whitespace.

Differences from Postgres Pro standard `CHAR` and `VARCHAR` are:

- Case insensitive comparison
- Handling of the whitespace at the end of string
- These types are always stored as two-byte unicode value regardless of database encoding.

F.33.2. Additional types

- `mchar` — analog of the MS SQL char type
- `mvarchar` — analog of the MS SQL varchar type

F.33.3. MCHAR and MVARCHAR features

- Defines `length(str)` function
- Defines `substr(str, pos[, length])` function
- Defines `||` operator, which would be applied to concatenate any (`mchar` and `mvarchar`) arguments
- Defines set of operators: `<`, `<=`, `=`, `>=`, `>` for case-insensitive comparison (ICU)
- Defines set of operators: `&<`, `&<=`, `&=`, `&>=`, `&>` to case-sensitive comparison (ICU)
- Implicit cast between `mchar` and `mvarchar` types
- B-tree and Hash-index support
- The `LIKE [ESCAPE]` operator support
- The `SIMILAR TO [ESCAPE]` operator support
- The `~` operator (POSIX regexp) support
- Index support for the `LIKE` operator

F.33.4. Authors

Oleg Bartunov <oleg@sai.msu.ru>
Teodor Sigaev <teodor@sigaev.ru>

F.34. online_analyze — update statistics after INSERT, UPDATE, DELETE, SELECT INTO, or COPY operations

The `online_analyze` module provides a set of features that immediately update statistics after `INSERT`, `UPDATE`, `DELETE`, `SELECT INTO`, or `COPY` operations for the affected tables.

F.34.1. Module Loading

To use `online_analyze` module, load the shared library:

```
LOAD 'online_analyze';
```

F.34.2. Module Configuration

You can configure `online_analyze` using the following custom variables (default values are shown):

- `online_analyze.enable = on`

Enables `online_analyze`.

- `online_analyze.verbose = on`

Executes `ANALYZE VERBOSE`.

Note

Since `verbose` is a reserved SQL key word, this parameter has to be double-quoted when used in SQL queries. For example:

```
ALTER SYSTEM SET "online_analyze.verbose" = 'off';
```

- `online_analyze.scale_factor = 0.1`

Fraction of table size to start online analysis (similar to [autovacuum_analyze_scale_factor](#)).

- `online_analyze.threshold = 50`

Minimum number of row updates before starting online analysis (similar to [autovacuum_analyze_threshold](#)).

- `online_analyze.min_interval = 10000`

Minimum time interval between `ANALYZE` calls per table, in milliseconds.

- `online_analyze.table_type = "all"`

Type(s) of tables for online analysis. Possible values are: `all`, `persistent`, `temporary`, `none`.

- `online_analyze.exclude_tables = ""`

List of tables to exclude from online analysis.

- `online_analyze.include_tables = ""`

List of tables to include in online analysis (`online_analyze.include_tables` overrides `online_analyze.exclude_tables`).

- `online_analyze.local_tracking = off`

Enables per-backend tracking for temporary tables by `online_analyze`. When this variable is set to `off`, `online_analyze` uses the default system statistics for temporary tables.

- `online_analyze.lower_limit = 0`

Minimum number of rows in a table required to trigger `online_analyze`.

- `online_analyze.capacity_threshold = 100000`

Maximum number of temporary tables to store in local cache.

F.34.3. Authors

Teodor Sigaev <teodor@sigaev.ru>

F.35. **old_snapshot** — inspect `old_snapshot_threshold` state

The `old_snapshot` module allows inspection of the server state that is used to implement [old_snapshot_threshold](#).

F.35.1. Functions

`pg_old_snapshot_time_mapping(array_offset OUT int4, end_timestamp OUT timestampz, newest_xmin OUT xid)` returns setof record

Returns all of the entries in the server's timestamp to XID mapping. Each entry represents the newest xmin of any snapshot taken in the corresponding minute.

F.36. pageinspect — low-level inspection of database pages

The `pageinspect` module provides functions that allow you to inspect the contents of database pages at a low level, which is useful for debugging purposes. All of these functions may be used only by superusers.

F.36.1. General Functions

`get_raw_page(relname text, fork text, blkno bigint)` returns `bytea`

`get_raw_page` reads the specified block of the named relation and returns a copy as a `bytea` value. This allows a single time-consistent copy of the block to be obtained. `fork` should be 'main' for the main data fork, 'fsm' for the [free space map](#), 'vm' for the [visibility map](#), or 'init' for the initialization fork.

`get_raw_page(relname text, blkno bigint)` returns `bytea`

A shorthand version of `get_raw_page`, for reading from the main fork. Equivalent to `get_raw_page(relname, 'main', blkno)`

`page_header(page bytea)` returns `record`

`page_header` shows fields that are common to all Postgres Pro heap and index pages.

A page image obtained with `get_raw_page` should be passed as argument. For example:

```
test=# SELECT * FROM page_header(get_raw_page('pg_class', 0));
   lsnn    | checksum | flags  | lower | upper | special | pagesize | version |
 prune_xid |-----+-----+-----+-----+-----+-----+-----+
+-----+
0/24A1B50 |         0 |      1 |   232 |   368 |       8192 |       8192 |         4 |
         0
```

The returned columns correspond to the fields in the `PageHeaderData` struct.

The `checksum` field is the checksum stored in the page, which might be incorrect if the page is somehow corrupted. If data checksums are not enabled for this instance, then the value stored is meaningless.

`page_checksum(page bytea, blkno bigint)` returns `smallint`

`page_checksum` computes the checksum for the page, as if it was located at the given block.

A page image obtained with `get_raw_page` should be passed as argument. For example:

```
test=# SELECT page_checksum(get_raw_page('pg_class', 0), 0);
 page_checksum
-----
         13443
```

Note that the checksum depends on the block number, so matching block numbers should be passed (except when doing esoteric debugging).

The checksum computed with this function can be compared with the `checksum` result field of the function `page_header`. If data checksums are enabled for this instance, then the two values should be equal.

`fsm_page_contents(page bytea)` returns `text`

`fsm_page_contents` shows the internal node structure of an FSM page. For example:

```
test=# SELECT fsm_page_contents(get_raw_page('pg_class', 'fsm', 0));
```

The output is a multiline string, with one line per node in the binary tree within the page. Only those nodes that are not zero are printed. The so-called "next" pointer, which points to the next slot to be returned from the page, is also printed.

F.36.2. Heap Functions

`heap_page_items(page bytea)` returns setof record

`heap_page_items` shows all line pointers on a heap page. For those line pointers that are in use, tuple headers as well as tuple raw data are also shown. All tuples are shown, whether or not the tuples were visible to an MVCC snapshot at the time the raw page was copied.

A heap page image obtained with `get_raw_page` should be passed as argument. For example:

```
test=# SELECT * FROM heap_page_items(get_raw_page('pg_class', 0));
```

The `heap_tuple_infomask_flags` function can be used to unpack the flag bits of `t_infomask` and `t_infomask2` for heap tuples.

`tuple_data_split(rel_oid oid, t_data bytea, t_infomask integer, t_infomask2 integer, t_bits text [, do_detoast bool])` returns bytea[]

`tuple_data_split` splits tuple data into attributes in the same way as backend internals.

```
test=# SELECT tuple_data_split('pg_class'::regclass, t_data, t_infomask,
    t_infomask2, t_bits) FROM heap_page_items(get_raw_page('pg_class', 0));
```

This function should be called with the same arguments as the return attributes of `heap_page_items`.

If `do_detoast` is true, attributes will be detoasted as needed. Default value is false.

`heap_page_item_attrs(page bytea, rel_oid regclass [, do_detoast bool])` returns setof record

`heap_page_item_attrs` is equivalent to `heap_page_items` except that it returns tuple raw data as an array of attributes that can optionally be detoasted by `do_detoast` which is false by default.

A heap page image obtained with `get_raw_page` should be passed as argument. For example:

```
test=# SELECT * FROM heap_page_item_attrs(get_raw_page('pg_class', 0),
    'pg_class'::regclass);
```

`heap_tuple_infomask_flags(t_infomask integer, t_infomask2 integer)` returns record

`heap_tuple_infomask_flags` decodes the `t_infomask` and `t_infomask2` returned by `heap_page_items` into a human-readable set of arrays made of flag names, with one column for all the flags and one column for combined flags. For example:

```
test=# SELECT t_ctid, raw_flags, combined_flags
    FROM heap_page_items(get_raw_page('pg_class', 0)),
    LATERAL heap_tuple_infomask_flags(t_infomask, t_infomask2)
    WHERE t_infomask IS NOT NULL OR t_infomask2 IS NOT NULL;
```

This function should be called with the same arguments as the return attributes of `heap_page_items`.

Combined flags are displayed for source-level macros that take into account the value of more than one raw bit, such as `HEAP_XMIN_FROZEN`.

F.36.3. B-Tree Functions

`bt_metap(relname text)` returns record

`bt_metap` returns information about a B-tree index's metapage. For example:

Additional Supplied Modules
and Extensions Shipped in
postgrespro-std-16-contrib

```
test=# SELECT * FROM bt_metap('pg_cast_oid_index');
-[ RECORD 1 ]-----+-----
magic                | 340322
version              | 4
root                 | 1
level                | 0
fastroot             | 1
fastlevel            | 0
last_cleanup_num_delpages | 0
last_cleanup_num_tuples  | 230
allequalimage        | f
```

`bt_page_stats(relname text, blkno bigint)` returns record

`bt_page_stats` returns summary information about a data page of a B-tree index. For example:

```
test=# SELECT * FROM bt_page_stats('pg_cast_oid_index', 1);
-[ RECORD 1 ]+-----
blkno          | 1
type           | 1
live_items     | 224
dead_items     | 0
avg_item_size  | 16
page_size      | 8192
free_size      | 3668
btpo_prev      | 0
btpo_next      | 0
btpo_level     | 0
btpo_flags     | 3
```

`bt_multi_page_stats(relname text, blkno bigint, blk_count bigint)` returns setof record

`bt_multi_page_stats` returns the same information as `bt_page_stats`, but does so for each page of the range of pages beginning at `blkno` and extending for `blk_count` pages. If `blk_count` is negative, all pages from `blkno` to the end of the index are reported on. For example:

```
test=# SELECT * FROM bt_multi_page_stats('pg_proc_oid_index', 5, 2);
-[ RECORD 1 ]+-----
blkno          | 5
type           | 1
live_items     | 367
dead_items     | 0
avg_item_size  | 16
page_size      | 8192
free_size      | 808
btpo_prev      | 4
btpo_next      | 6
btpo_level     | 0
btpo_flags     | 1
-[ RECORD 2 ]+-----
blkno          | 6
type           | 1
live_items     | 367
dead_items     | 0
avg_item_size  | 16
page_size      | 8192
free_size      | 808
btpo_prev      | 5
btpo_next      | 7
btpo_level     | 0
```

btpo_flags | 1

bt_page_items(relname text, blkno bigint) returns setof record

bt_page_items returns detailed information about all of the items on a B-tree index page. For example:

```
test=# SELECT itemoffset, ctid, itemlen, nulls, vars, data, dead, htid, tids[0:2] AS
some_tids
        FROM bt_page_items('tenk2_hundred', 5);
 itemoffset |   ctid   | itemlen | nulls | vars |          data          | dead | htid |
-----+-----+-----+-----+-----+-----+-----+-----+
+-----+-----+-----+-----+-----+-----+-----+-----+
          1 | (16,1)   |    16   | f      | f     | 30 00 00 00 00 00 00 00 |      |      |
          2 | (16,8292)|   616   | f      | f     | 24 00 00 00 00 00 00 00 | f      |      |
(1,6)      | {"(1,6)","(10,22)"} |
          3 | (16,8292)|   616   | f      | f     | 25 00 00 00 00 00 00 00 | f      |      |
(1,18)     | {"(1,18)","(4,22)"} |
          4 | (16,8292)|   616   | f      | f     | 26 00 00 00 00 00 00 00 | f      |      |
(4,18)     | {"(4,18)","(6,17)"} |
          5 | (16,8292)|   616   | f      | f     | 27 00 00 00 00 00 00 00 | f      |      |
(1,2)      | {"(1,2)","(1,19)"} |
          6 | (16,8292)|   616   | f      | f     | 28 00 00 00 00 00 00 00 | f      |      |
(2,24)     | {"(2,24)","(4,11)"} |
          7 | (16,8292)|   616   | f      | f     | 29 00 00 00 00 00 00 00 | f      |      |
(2,17)     | {"(2,17)","(11,2)"} |
          8 | (16,8292)|   616   | f      | f     | 2a 00 00 00 00 00 00 00 | f      |      |
(0,25)     | {"(0,25)","(3,20)"} |
          9 | (16,8292)|   616   | f      | f     | 2b 00 00 00 00 00 00 00 | f      |      |

         10 | (16,8292)|   616   | f      | f     | 2c 00 00 00 00 00 00 00 | f      |      |
(1,3)      | {"(1,3)","(3,9)"} |
         11 | (16,8292)|   616   | f      | f     | 2d 00 00 00 00 00 00 00 | f      |      |
(6,28)     | {"(6,28)","(11,1)"} |
         12 | (16,8292)|   616   | f      | f     | 2e 00 00 00 00 00 00 00 | f      |      |
(0,27)     | {"(0,27)","(1,13)"} |
         13 | (16,8292)|   616   | f      | f     | 2f 00 00 00 00 00 00 00 | f      |      |
(4,17)     | {"(4,17)","(4,21)"} |
(13 rows)
```

This is a B-tree leaf page. All tuples that point to the table happen to be posting list tuples (all of which store a total of 100 6 byte TIDs). There is also a “high key” tuple at itemoffset number 1. ctid is used to store encoded information about each tuple in this example, though leaf page tuples often store a heap TID directly in the ctid field instead. tids is the list of TIDs stored as a posting list.

In an internal page (not shown), the block number part of ctid is a “downlink”, which is a block number of another page in the index itself. The offset part (the second number) of ctid stores encoded information about the tuple, such as the number of columns present (suffix truncation may have removed unneeded suffix columns). Truncated columns are treated as having the value “minus infinity”.

htid shows a heap TID for the tuple, regardless of the underlying tuple representation. This value may match ctid, or may be decoded from the alternative representations used by posting list tuples and tuples from internal pages. Tuples in internal pages usually have the implementation level heap TID column truncated away, which is represented as a NULL htid value.

Note that the first item on any non-rightmost page (any page with a non-zero value in the btpo_next field) is the page’s “high key”, meaning its data serves as an upper bound on all items appearing on

the page, while its `ctid` field does not point to another block. Also, on internal pages, the first real data item (the first item that is not a high key) reliably has every column truncated away, leaving no actual value in its `data` field. Such an item does have a valid downlink in its `ctid` field, however.

For more details about the structure of B-tree indexes, see [Section 64.4.1](#). For more details about deduplication and posting lists, see [Section 64.4.3](#).

`bt_page_items(page bytea)` returns `setof record`

It is also possible to pass a page to `bt_page_items` as a `bytea` value. A page image obtained with `get_raw_page` should be passed as argument. So the last example could also be rewritten like this:

```
test=# SELECT itemoffset, ctid, itemlen, nulls, vars, data, dead, htid, tids[0:2] AS
some_tids
      FROM bt_page_items(get_raw_page('tenk2_hundred', 5));
 itemoffset |      ctid      | itemlen | nulls | vars |          data          | dead |
 htid  |      some_tids
-----+-----+-----+-----+-----+-----+-----+-----+-----+
1 | (16,1) | 16 | f | f | 30 00 00 00 00 00 00 00 | f |
(1,6) | {"(1,6)","(10,22)"}
3 | (16,8292) | 616 | f | f | 24 00 00 00 00 00 00 00 | f |
(1,18) | {"(1,18)","(4,22)"}
4 | (16,8292) | 616 | f | f | 25 00 00 00 00 00 00 00 | f |
(4,18) | {"(4,18)","(6,17)"}
5 | (16,8292) | 616 | f | f | 26 00 00 00 00 00 00 00 | f |
(1,2) | {"(1,2)","(1,19)"}
6 | (16,8292) | 616 | f | f | 27 00 00 00 00 00 00 00 | f |
(2,24) | {"(2,24)","(4,11)"}
7 | (16,8292) | 616 | f | f | 28 00 00 00 00 00 00 00 | f |
(2,17) | {"(2,17)","(11,2)"}
8 | (16,8292) | 616 | f | f | 2a 00 00 00 00 00 00 00 | f |
(0,25) | {"(0,25)","(3,20)"}
9 | (16,8292) | 616 | f | f | 2b 00 00 00 00 00 00 00 | f |
(0,10) | {"(0,10)","(0,14)"}
10 | (16,8292) | 616 | f | f | 2c 00 00 00 00 00 00 00 | f |
(1,3) | {"(1,3)","(3,9)"}
11 | (16,8292) | 616 | f | f | 2d 00 00 00 00 00 00 00 | f |
(6,28) | {"(6,28)","(11,1)"}
12 | (16,8292) | 616 | f | f | 2e 00 00 00 00 00 00 00 | f |
(0,27) | {"(0,27)","(1,13)"}
13 | (16,8292) | 616 | f | f | 2f 00 00 00 00 00 00 00 | f |
(4,17) | {"(4,17)","(4,21)"}
(13 rows)
```

All the other details are the same as explained in the previous item.

F.36.4. BRIN Functions

`brin_page_type(page bytea)` returns `text`

`brin_page_type` returns the page type of the given BRIN index page, or throws an error if the page is not a valid BRIN page. For example:

```
test=# SELECT brin_page_type(get_raw_page('brinidx', 0));
 brin_page_type
-----
 meta
```

`brin_metapage_info(page bytea)` returns record

`brin_metapage_info` returns assorted information about a BRIN index metapage. For example:

```
test=# SELECT * FROM brin_metapage_info(get_raw_page('brinidx', 0));
   magic   | version | pagesperpage | lastrevmappage
-----+-----+-----+-----
0xA8109CFA |      1 |           4 |              2
```

`brin_revmap_data(page bytea)` returns setof tid

`brin_revmap_data` returns the list of tuple identifiers in a BRIN index range map page. For example:

```
test=# SELECT * FROM brin_revmap_data(get_raw_page('brinidx', 2)) LIMIT 5;
   pages
-----
(6,137)
(6,138)
(6,139)
(6,140)
(6,141)
```

`brin_page_items(page bytea, index oid)` returns setof record

`brin_page_items` returns the data stored in the BRIN data page. For example:

```
test=# SELECT * FROM brin_page_items(get_raw_page('brinidx', 5),
                                     'brinidx')
      ORDER BY blknum, attnum LIMIT 6;
 itemoffset | blknum | attnum | allnulls | hasnulls | placeholder | empty | value
-----+-----+-----+-----+-----+-----+-----+-----
137 |      0 |      1 | t         | f         | f           | f     |
137 |      0 |      2 | f         | f         | f           | f     | {1 ..
88}
138 |      4 |      1 | t         | f         | f           | f     |
138 |      4 |      2 | f         | f         | f           | f     | {89 ..
176}
139 |      8 |      1 | t         | f         | f           | f     |
139 |      8 |      2 | f         | f         | f           | f     | {177 ..
264}
```

The returned columns correspond to the fields in the `BrinMemTuple` and `BrinValues` structs.

F.36.5. GIN Functions

`gin_metapage_info(page bytea)` returns record

`gin_metapage_info` returns information about a GIN index metapage. For example:

```
test=# SELECT * FROM gin_metapage_info(get_raw_page('gin_index', 0));
-[ RECORD 1 ]-----+-----
pending_head      | 4294967295
pending_tail      | 4294967295
tail_free_size    | 0
n_pending_pages   | 0
n_pending_tuples  | 0
n_total_pages     | 7
n_entry_pages     | 6
n_data_pages      | 0
n_entries         | 693
version           | 2
```

`gin_page_opaque_info(page bytea)` returns record

`gin_page_opaque_info` returns information about a GIN index opaque area, like the page type. For example:

```
test=# SELECT * FROM gin_page_opaque_info(get_raw_page('gin_index', 2));
 rightlink | maxoff | flags
-----+-----+-----
          5 |        0 | {data,leaf,compressed}
(1 row)
```

`gin_leafpage_items(page bytea)` returns setof record

`gin_leafpage_items` returns information about the data stored in a GIN leaf page. For example:

```
test=# SELECT first_tid, nbytes, tids[0:5] AS some_tids
       FROM gin_leafpage_items(get_raw_page('gin_test_idx', 2));
 first_tid | nbytes | some_tids
-----+-----+-----
(8,41)    |    244 | {"(8,41)","(8,43)","(8,44)","(8,45)","(8,46)"}
(10,45)    |    248 | {"(10,45)","(10,46)","(10,47)","(10,48)","(10,49)"}
(12,52)    |    248 | {"(12,52)","(12,53)","(12,54)","(12,55)","(12,56)"}
(14,59)    |    320 | {"(14,59)","(14,60)","(14,61)","(14,62)","(14,63)"}
(167,16)   |    376 | {"(167,16)","(167,17)","(167,18)","(167,19)","(167,20)"}
(170,30)   |    376 | {"(170,30)","(170,31)","(170,32)","(170,33)","(170,34)"}
(173,44)   |    197 | {"(173,44)","(173,45)","(173,46)","(173,47)","(173,48)"}
(7 rows)
```

F.36.6. GiST Functions

`gist_page_opaque_info(page bytea)` returns record

`gist_page_opaque_info` returns information from a GiST index page's opaque area, such as the NSN, rightlink and page type. For example:

```
test=# SELECT * FROM gist_page_opaque_info(get_raw_page('test_gist_idx', 2));
 lsn | nsn | rightlink | flags
-----+-----+-----+-----
 0/1 | 0/0 |          1 | {leaf}
(1 row)
```

`gist_page_items(page bytea, index_oid regclass)` returns setof record

`gist_page_items` returns information about the data stored in a page of a GiST index. For example:

```
test=# SELECT * FROM gist_page_items(get_raw_page('test_gist_idx', 0),
 'test_gist_idx');
 itemoffset | ctid   | itemlen | dead | keys
-----+-----+-----+-----+-----
          1 | (1,65535) |    40 | f    | (p)=("(185,185),(1,1)")
          2 | (2,65535) |    40 | f    | (p)=("(370,370),(186,186)")
          3 | (3,65535) |    40 | f    | (p)=("(555,555),(371,371)")
          4 | (4,65535) |    40 | f    | (p)=("(740,740),(556,556)")
          5 | (5,65535) |    40 | f    | (p)=("(870,870),(741,741)")
          6 | (6,65535) |    40 | f    | (p)=("(1000,1000),(871,871)")
(6 rows)
```

`gist_page_items_bytea(page bytea)` returns setof record

Same as `gist_page_items`, but returns the key data as a raw bytea blob. Since it does not attempt to decode the key, it does not need to know which index is involved. For example:

```
test=# SELECT * FROM gist_page_items_bytea(get_raw_page('test_gist_idx', 0));
 itemoffset | ctid   | itemlen | dead | key_data
-----+-----+-----+-----+-----
```

```

F.36.7. Hash Functions

`hash_page_type(page bytea)` returns text

`hash_page_type` returns page type of the given HASH index page. For example:

```

test=# SELECT hash_page_type(get_raw_page('con_hash_index', 0));
 hash_page_type
-----
metapage

```

`hash_page_stats(page bytea)` returns setof record

`hash_page_stats` returns information about a bucket or overflow page of a HASH index. For example:

```

test=# SELECT * FROM hash_page_stats(get_raw_page('con_hash_index', 1));
-[ RECORD 1 ]-----+-----
live_items          | 407
dead_items          | 0
page_size           | 8192
free_size           | 8
hasho_prevblkno     | 4096
hasho_nextblkno     | 8474
hasho_bucket        | 0
hasho_flag           | 66
hasho_page_id       | 65408

```

`hash_page_items(page bytea)` returns setof record

`hash_page_items` returns information about the data stored in a bucket or overflow page of a HASH index page. For example:

```

test=# SELECT * FROM hash_page_items(get_raw_page('con_hash_index', 1)) LIMIT 5;
 itemoffset |   ctid   |   data
-----+-----+-----
1 | (899,77) | 1053474816
2 | (897,29) | 1053474816
3 | (894,207)| 1053474816
4 | (892,159)| 1053474816
5 | (890,111)| 1053474816

```

`hash_bitmap_info(index oid, blkno bigint)` returns record

`hash_bitmap_info` shows the status of a bit in the bitmap page for a particular overflow page of HASH index. For example:

Additional Supplied Modules
and Extensions Shipped in
postgrespro-std-16-contrib

```
test=# SELECT * FROM hash_bitmap_info('con_hash_index', 2052);
 bitmapblkno | bitmapbit | bitstatus
-----+-----+-----
          65 |          3 | t
```

hash_metapage_info(page bytea) returns record

hash_metapage_info returns information stored in the meta page of a HASH index. For example:

```
test=# SELECT magic, version, ntuples, ffactor, bsize, bmsize, bmshift,
test-#         maxbucket, highmask, lowmask, ovflpoint, firstfree, nmaps, procid,
test-#         regexp_replace(spares::text, '(\,0)*}', '{}') as spares,
test-#         regexp_replace(mapp::text, '(\,0)*}', '{}') as mapp
test=# FROM hash_metapage_info(get_raw_page('con_hash_index', 0));
-[ RECORD 1 ]-----
 magic      | 105121344
 version    | 4
 ntuples    | 500500
 ffactor    | 40
 bsize      | 8152
 bmsize     | 4096
 bmshift    | 15
 maxbucket  | 12512
 highmask   | 16383
 lowmask    | 8191
 ovflpoint  | 28
 firstfree  | 1204
 nmaps      | 1
 procid     | 450
 spares     | {0,0,0,0,0,0,1,1,1,1,1,1,1,1,3,4,4,4,45,55,58,59,
508,567,628,704,1193,1202,1204}
 mapp       | {65}
```

F.37. passwordcheck — verify password strength

The `passwordcheck` module checks users' passwords whenever they are set with [CREATE ROLE](#) or [ALTER ROLE](#) (it doesn't work, if a non-default profile is assigned to the user). If a password is considered too weak, it will be rejected and the command will terminate with an error.

To enable this module, add '`$libdir/passwordcheck`' to [shared_preload_libraries](#) in `postgresql.conf`, then restart the server.

Caution

To prevent unencrypted passwords from being sent across the network, written to the server log or otherwise stolen by a database administrator, Postgres Pro allows the user to supply pre-encrypted passwords. Many client programs make use of this functionality and encrypt the password before sending it to the server.

This limits the usefulness of the `passwordcheck` module, because in that case it can only try to guess the password. For this reason, `passwordcheck` is not recommended if your security requirements are high. It is more secure to use an external authentication method such as GSSAPI (see [Chapter 19](#)) than to rely on passwords within the database.

F.38. pg_buffercache — inspect Postgres Pro buffer cache state

The `pg_buffercache` module provides a means for examining what's happening in the shared buffer cache in real time.

This module provides the `pg_buffercache_pages()` function (wrapped in the `pg_buffercache` view), the `pg_buffercache_summary()` function, and the `pg_buffercache_usage_counts()` function.

The `pg_buffercache_pages()` function returns a set of records, each row describing the state of one shared buffer entry. The `pg_buffercache` view wraps the function for convenient use.

The `pg_buffercache_summary()` function returns a single row summarizing the state of the shared buffer cache.

The `pg_buffercache_usage_counts()` function returns a set of records, each row describing the number of buffers with a given usage count.

By default, use is restricted to superusers and roles with privileges of the `pg_monitor` role. Access may be granted to others using `GRANT`.

F.38.1. The pg_buffercache View

The definitions of the columns exposed by the view are shown in [Table F.20](#).

Table F.20. pg_buffercache Columns

Column Type	Description
<code>bufferid integer</code>	ID, in the range 1.. <code>shared_buffers</code>
<code>relfilenode oid (references pg_class .relfilenode)</code>	Filenode number of the relation
<code>reltablespace oid (references pg_tablespace .oid)</code>	Tablespace OID of the relation
<code>reldatabase oid (references pg_database .oid)</code>	Database OID of the relation
<code>relforknumber smallint</code>	Fork number within the relation
<code>relblocknumber bigint</code>	Page number within the relation
<code>isdirty boolean</code>	Is the page dirty?
<code>usagecount smallint</code>	Clock-sweep access count
<code>pinning_backends integer</code>	Number of backends pinning this buffer

There is one row for each buffer in the shared cache. Unused buffers are shown with all fields null except `bufferid`. Shared system catalogs are shown as belonging to database zero.

Because the cache is shared by all the databases, there will normally be pages from relations not belonging to the current database. This means that there may not be matching join rows in `pg_class` for some rows, or that there could even be incorrect joins. If you are trying to join against `pg_class`, it's a good idea to restrict the join to rows having `reldatabase` equal to the current database's OID or zero.

Since buffer manager locks are not taken to copy the buffer state data that the view will display, accessing `pg_buffercache` view has less impact on normal buffer activity but it doesn't provide a consistent set of results across all buffers. However, we ensure that the information of each buffer is self-consistent.

F.38.2. The `pg_buffercache_summary()` Function

The definitions of the columns exposed by the function are shown in [Table F.21](#).

Table F.21. `pg_buffercache_summary()` Output Columns

Column Type	Description
<code>buffers_used int4</code>	Number of used shared buffers
<code>buffers_unused int4</code>	Number of unused shared buffers
<code>buffers_dirty int4</code>	Number of dirty shared buffers
<code>buffers_pinned int4</code>	Number of pinned shared buffers
<code>usagecount_avg float8</code>	Average usage count of used shared buffers

The `pg_buffercache_summary()` function returns a single row summarizing the state of all shared buffers. Similar and more detailed information is provided by the `pg_buffercache` view, but `pg_buffercache_summary()` is significantly cheaper.

Like the `pg_buffercache` view, `pg_buffercache_summary()` does not acquire buffer manager locks. Therefore concurrent activity can lead to minor inaccuracies in the result.

F.38.3. The `pg_buffercache_usage_counts()` Function

The definitions of the columns exposed by the function are shown in [Table F.22](#).

Table F.22. `pg_buffercache_usage_counts()` Output Columns

Column Type	Description
<code>usage_count int4</code>	A possible buffer usage count
<code>buffers int4</code>	Number of buffers with the usage count
<code>dirty int4</code>	Number of dirty buffers with the usage count
<code>pinned int4</code>	Number of pinned buffers with the usage count

The `pg_buffercache_usage_counts()` function returns a set of rows summarizing the states of all shared buffers, aggregated over the possible usage count values. Similar and more detailed information is provided by the `pg_buffercache` view, but `pg_buffercache_usage_counts()` is significantly cheaper.

Like the `pg_buffercache` view, `pg_buffercache_usage_counts()` does not acquire buffer manager locks. Therefore concurrent activity can lead to minor inaccuracies in the result.

F.38.4. Sample Output

```
regression=# SELECT n.nspname, c.relname, count(*) AS buffers
```

Additional Supplied Modules and Extensions Shipped in postgrespro-std-16-contrib

```
FROM pg_buffercache b JOIN pg_class c

F.38.5. Authors

Mark Kirkwood <markir@paradise.net.nz>

Design suggestions: Neil Conway <neilc@samurai.com>

Debugging advice: Tom Lane <tgl@sss.pgh.pa.us>

F.39. pgcrypto — cryptographic functions

The `pgcrypto` module provides cryptographic functions for Postgres Pro.

This module is considered “trusted”, that is, it can be installed by non-superusers who have `CREATE` privilege on the current database.

`pgcrypto` requires OpenSSL and won't be installed if OpenSSL support was not selected when Postgres Pro was built.

F.39.1. General Hashing Functions

F.39.1.1. `digest()`

`digest(data text, type text)` returns `bytea`
`digest(data bytea, type text)` returns `bytea`

Computes a binary hash of the given *data*. *type* is the algorithm to use. Standard algorithms are `md5`, `sha1`, `sha224`, `sha256`, `sha384` and `sha512`. Moreover, any digest algorithm OpenSSL supports is automatically picked up.

If you want the digest as a hexadecimal string, use `encode()` on the result. For example:

```
CREATE OR REPLACE FUNCTION sha1(bytea) returns text AS $$  
    SELECT encode(digest($1, 'sha1'), 'hex')  
$$ LANGUAGE SQL STRICT IMMUTABLE;
```

F.39.1.2. `hmac()`

`hmac(data text, key text, type text)` returns `bytea`
`hmac(data bytea, key bytea, type text)` returns `bytea`

Calculates hashed MAC for *data* with key *key*. *type* is the same as in `digest()`.

This is similar to `digest()` but the hash can only be recalculated knowing the key. This prevents the scenario of someone altering data and also changing the hash to match.

If the key is larger than the hash block size it will first be hashed and the result will be used as key.

F.39.2. Password Hashing Functions

The functions `crypt()` and `gen_salt()` are specifically designed for hashing passwords. `crypt()` does the hashing and `gen_salt()` prepares algorithm parameters for it.

The algorithms in `crypt()` differ from the usual MD5 or SHA1 hashing algorithms in the following respects:

1. They are slow. As the amount of data is so small, this is the only way to make brute-forcing passwords hard.
2. They use a random value, called the *salt*, so that users having the same password will have different encrypted passwords. This is also an additional defense against reversing the algorithm.
3. They include the algorithm type in the result, so passwords hashed with different algorithms can co-exist.
4. Some of them are adaptive — that means when computers get faster, you can tune the algorithm to be slower, without introducing incompatibility with existing passwords.

[Table F.23](#) lists the algorithms supported by the `crypt()` function.

Table F.23. Supported Algorithms for `crypt()`

Algorithm	Max Password Length	Adaptive?	Salt Bits	Output Length	Description
bf	72	yes	128	60	Blowfish-based, variant 2a
md5	unlimited	no	48	34	MD5-based crypt
xdes	8	yes	24	20	Extended DES
des	8	no	12	13	Original UNIX crypt

F.39.2.1. `crypt()`

`crypt(password text, salt text)` returns text

Calculates a crypt(3)-style hash of *password*. When storing a new password, you need to use `gen_salt()` to generate a new *salt* value. To check a password, pass the stored hash value as *salt*, and test whether the result matches the stored value.

Example of setting a new password:

```
UPDATE ... SET pswhash = crypt('new password', gen_salt('md5'));
```

Example of authentication:

```
SELECT (pswhash = crypt('entered password', pswhash)) AS pswmatch FROM ... ;
```

This returns `true` if the entered password is correct.

F.39.2.2. `gen_salt()`

`gen_salt(type text [, iter_count integer])` returns text

Generates a new random salt string for use in `crypt()`. The salt string also tells `crypt()` which algorithm to use.

The *type* parameter specifies the hashing algorithm. The accepted types are: `des`, `xdes`, `md5` and `bf`.

The *iter_count* parameter lets the user specify the iteration count, for algorithms that have one. The higher the count, the more time it takes to hash the password and therefore the more time to break it. Although with too high a count the time to calculate a hash may be several years — which is somewhat impractical. If the *iter_count* parameter is omitted, the default iteration count is used. Allowed values for *iter_count* depend on the algorithm and are shown in [Table F.24](#).

Table F.24. Iteration Counts for `crypt()`

Algorithm	Default	Min	Max
xdes	725	1	16777215
bf	6	4	31

For `xdes` there is an additional limitation that the iteration count must be an odd number.

To pick an appropriate iteration count, consider that the original DES crypt was designed to have the speed of 4 hashes per second on the hardware of that time. Slower than 4 hashes per second would probably dampen usability. Faster than 100 hashes per second is probably too fast.

[Table F.25](#) gives an overview of the relative slowness of different hashing algorithms. The table shows how much time it would take to try all combinations of characters in an 8-character password, assuming that the password contains either only lower case letters, or upper- and lower-case letters and numbers. In the `crypt-bf` entries, the number after a slash is the *iter_count* parameter of `gen_salt`.

Table F.25. Hash Algorithm Speeds

Algorithm	Hashes/sec	For [a-z]	For [A-Za-z0-9]	Duration relative to md5 hash
crypt-bf/8	1792	4 years	3927 years	100k
crypt-bf/7	3648	2 years	1929 years	50k
crypt-bf/6	7168	1 year	982 years	25k
crypt-bf/5	13504	188 days	521 years	12.5k
crypt-md5	171584	15 days	41 years	1k
crypt-des	23221568	157.5 minutes	108 days	7
sha1	37774272	90 minutes	68 days	4
md5 (hash)	150085504	22.5 minutes	17 days	1

Notes:

- The machine used is an Intel Mobile Core i3.
- `crypt-des` and `crypt-md5` algorithm numbers are taken from John the Ripper v1.6.38 `-test` output.
- `md5 hash` numbers are from `mdcrack 1.2`.
- `sha1` numbers are from `lcrack-20031130-beta`.
- `crypt-bf` numbers are taken using a simple program that loops over 1000 8-character passwords. That way the speed with different numbers of iterations can be shown. For reference: `john -test` shows 13506 loops/sec for `crypt-bf/5`. (The very small difference in results is in accordance with the fact that the `crypt-bf` implementation in `pgcrypto` is the same one used in John the Ripper.)

Note that “try all combinations” is not a realistic exercise. Usually password cracking is done with the help of dictionaries, which contain both regular words and various mutations of them. So, even somewhat word-like passwords could be cracked much faster than the above numbers suggest, while a 6-character non-word-like password may escape cracking. Or not.

F.39.3. PGP Encryption Functions

The functions here implement the encryption part of the OpenPGP ([RFC 4880](#)) standard. Supported are both symmetric-key and public-key encryption.

An encrypted PGP message consists of 2 parts, or *packets*:

- Packet containing a session key — either symmetric-key or public-key encrypted.
- Packet containing data encrypted with the session key.

When encrypting with a symmetric key (i.e., a password):

1. The given password is hashed using a String2Key (S2K) algorithm. This is rather similar to `crypt()` algorithms — purposefully slow and with random salt — but it produces a full-length binary key.
2. If a separate session key is requested, a new random key will be generated. Otherwise the S2K key will be used directly as the session key.
3. If the S2K key is to be used directly, then only S2K settings will be put into the session key packet. Otherwise the session key will be encrypted with the S2K key and put into the session key packet.

When encrypting with a public key:

1. A new random session key is generated.
2. It is encrypted using the public key and put into the session key packet.

In either case the data to be encrypted is processed as follows:

1. Optional data-manipulation: compression, conversion to UTF-8, and/or conversion of line-endings.
2. The data is prefixed with a block of random bytes. This is equivalent to using a random IV.
3. A SHA1 hash of the random prefix and data is appended.
4. All this is encrypted with the session key and placed in the data packet.

F.39.3.1. `pgp_sym_encrypt()`

`pgp_sym_encrypt(data text, psw text [, options text])` returns `bytea`
`pgp_sym_encrypt_bytea(data bytea, psw text [, options text])` returns `bytea`

Encrypt *data* with a symmetric PGP key *psw*. The *options* parameter can contain option settings, as described below.

F.39.3.2. `pgp_sym_decrypt()`

`pgp_sym_decrypt(msg bytea, psw text [, options text])` returns `text`
`pgp_sym_decrypt_bytea(msg bytea, psw text [, options text])` returns `bytea`

Decrypt a symmetric-key-encrypted PGP message.

Decrypting `bytea` data with `pgp_sym_decrypt` is disallowed. This is to avoid outputting invalid character data. Decrypting originally textual data with `pgp_sym_decrypt_bytea` is fine.

The *options* parameter can contain option settings, as described below.

F.39.3.3. `pgp_pub_encrypt()`

`pgp_pub_encrypt(data text, key bytea [, options text])` returns `bytea`
`pgp_pub_encrypt_bytea(data bytea, key bytea [, options text])` returns `bytea`

Encrypt *data* with a public PGP key *key*. Giving this function a secret key will produce an error.

The *options* parameter can contain option settings, as described below.

F.39.3.4. `pgp_pub_decrypt()`

`pgp_pub_decrypt(msg bytea, key bytea [, psw text [, options text]])` returns `text`
`pgp_pub_decrypt_bytea(msg bytea, key bytea [, psw text [, options text]])` returns `bytea`

Decrypt a public-key-encrypted message. *key* must be the secret key corresponding to the public key that was used to encrypt. If the secret key is password-protected, you must give the password in *psw*. If there is no password, but you want to specify options, you need to give an empty password.

Decrypting `bytea` data with `pgp_pub_decrypt` is disallowed. This is to avoid outputting invalid character data. Decrypting originally textual data with `pgp_pub_decrypt_bytea` is fine.

The *options* parameter can contain option settings, as described below.

F.39.3.5. `pgp_key_id()`

`pgp_key_id(bytea)` returns `text`

`pgp_key_id` extracts the key ID of a PGP public or secret key. Or it gives the key ID that was used for encrypting the data, if given an encrypted message.

It can return 2 special key IDs:

- `SYMKEY`

The message is encrypted with a symmetric key.

- `ANYKEY`

The message is public-key encrypted, but the key ID has been removed. That means you will need to try all your secret keys on it to see which one decrypts it. `pgcrypto` itself does not produce such messages.

Note that different keys may have the same ID. This is rare but a normal event. The client application should then try to decrypt with each one, to see which fits — like handling `ANYKEY`.

F.39.3.6. `armor()`, `dearmor()`

```
armor(data bytea [ , keys text[], values text[] ]) returns text
dearmor(data text) returns bytea
```

These functions wrap/unwrap binary data into PGP ASCII-armor format, which is basically Base64 with CRC and additional formatting.

If the *keys* and *values* arrays are specified, an *armor header* is added to the armored format for each key/value pair. Both arrays must be single-dimensional, and they must be of the same length. The keys and values cannot contain any non-ASCII characters.

F.39.3.7. `pgp_armor_headers`

```
pgp_armor_headers(data text, key out text, value out text) returns setof record
```

`pgp_armor_headers()` extracts the armor headers from *data*. The return value is a set of rows with two columns, key and value. If the keys or values contain any non-ASCII characters, they are treated as UTF-8.

F.39.3.8. Options for PGP Functions

Options are named to be similar to GnuPG. An option's value should be given after an equal sign; separate options from each other with commas. For example:

```
pgp_sym_encrypt(data, psw, 'compress-algo=1, cipher-algo=aes256')
```

All of the options except `convert-crlf` apply only to encrypt functions. Decrypt functions get the parameters from the PGP data.

The most interesting options are probably `compress-algo` and `unicode-mode`. The rest should have reasonable defaults.

F.39.3.8.1. `cipher-algo`

Which cipher algorithm to use.

Values: `bf`, `aes128`, `aes192`, `aes256`, `3des`, `cast5`

Default: `aes128`

Applies to: `pgp_sym_encrypt`, `pgp_pub_encrypt`

F.39.3.8.2. `compress-algo`

Which compression algorithm to use. Only available if Postgres Pro was built with `zlib`.

Values:

0 - no compression

1 - ZIP compression

2 - ZLIB compression (= ZIP plus meta-data and block CRCs)

Default: 0

Applies to: `pgp_sym_encrypt`, `pgp_pub_encrypt`

F.39.3.8.3. `compress-level`

How much to compress. Higher levels compress smaller but are slower. 0 disables compression.

Values: 0, 1-9

Default: 6

Applies to: pgp_sym_encrypt, pgp_pub_encrypt

F.39.3.8.4. convert-crlf

Whether to convert `\n` into `\r\n` when encrypting and `\r\n` to `\n` when decrypting. RFC 4880 specifies that text data should be stored using `\r\n` line-feeds. Use this to get fully RFC-compliant behavior.

Values: 0, 1

Default: 0

Applies to: pgp_sym_encrypt, pgp_pub_encrypt, pgp_sym_decrypt, pgp_pub_decrypt

F.39.3.8.5. disable-mdc

Do not protect data with SHA-1. The only good reason to use this option is to achieve compatibility with ancient PGP products, predating the addition of SHA-1 protected packets to RFC 4880. Recent gnupg.org and pgp.com software supports it fine.

Values: 0, 1

Default: 0

Applies to: pgp_sym_encrypt, pgp_pub_encrypt

F.39.3.8.6. sess-key

Use separate session key. Public-key encryption always uses a separate session key; this option is for symmetric-key encryption, which by default uses the S2K key directly.

Values: 0, 1

Default: 0

Applies to: pgp_sym_encrypt

F.39.3.8.7. s2k-mode

Which S2K algorithm to use.

Values:

0 - Without salt. Dangerous!

1 - With salt but with fixed iteration count.

3 - Variable iteration count.

Default: 3

Applies to: pgp_sym_encrypt

F.39.3.8.8. s2k-count

The number of iterations of the S2K algorithm to use. It must be a value between 1024 and 65011712, inclusive.

Default: A random value between 65536 and 253952

Applies to: pgp_sym_encrypt, only with s2k-mode=3

F.39.3.8.9. s2k-digest-algo

Which digest algorithm to use in S2K calculation.

Values: md5, sha1

Default: sha1

Applies to: pgp_sym_encrypt

F.39.3.8.10. s2k-cipher-algo

Which cipher to use for encrypting separate session key.

Values: bf, aes, aes128, aes192, aes256

Default: use cipher-algo

Applies to: pgp_sym_encrypt

F.39.3.8.11. unicode-mode

Whether to convert textual data from database internal encoding to UTF-8 and back. If your database already is UTF-8, no conversion will be done, but the message will be tagged as UTF-8. Without this option it will not be.

Values: 0, 1

Default: 0

Applies to: `pgp_sym_encrypt`, `pgp_pub_encrypt`

F.39.3.9. Generating PGP Keys with GnuPG

To generate a new key:

```
gpg --gen-key
```

The preferred key type is “DSA and Elgamal”.

For RSA encryption you must create either DSA or RSA sign-only key as master and then add an RSA encryption subkey with `gpg --edit-key`.

To list keys:

```
gpg --list-secret-keys
```

To export a public key in ASCII-armor format:

```
gpg -a --export KEYID > public.key
```

To export a secret key in ASCII-armor format:

```
gpg -a --export-secret-keys KEYID > secret.key
```

You need to use `dearmor()` on these keys before giving them to the PGP functions. Or if you can handle binary data, you can drop `-a` from the command.

For more details see `man gpg`, *The GNU Privacy Handbook* and other documentation on <https://www.gnupg.org/>.

F.39.3.10. Limitations of PGP Code

- No support for signing. That also means that it is not checked whether the encryption subkey belongs to the master key.
- No support for encryption key as master key. As such practice is generally discouraged, this should not be a problem.
- No support for several subkeys. This may seem like a problem, as this is common practice. On the other hand, you should not use your regular GPG/PGP keys with `pgcrypto`, but create new ones, as the usage scenario is rather different.

F.39.4. Raw Encryption Functions

These functions only run a cipher over data; they don't have any advanced features of PGP encryption. Therefore they have some major problems:

1. They use user key directly as cipher key.
2. They don't provide any integrity checking, to see if the encrypted data was modified.
3. They expect that users manage all encryption parameters themselves, even IV.
4. They don't handle text.

So, with the introduction of PGP encryption, usage of raw encryption functions is discouraged.

`encrypt(data bytea, key bytea, type text)` returns `bytea`
`decrypt(data bytea, key bytea, type text)` returns `bytea`

`encrypt_iv(data bytea, key bytea, iv bytea, type text)` returns `bytea`
`decrypt_iv(data bytea, key bytea, iv bytea, type text)` returns `bytea`

Encrypt/decrypt data using the cipher method specified by *type*. The syntax of the *type* string is:

`algorithm [ - mode ] [ /pad: padding ]`

where *algorithm* is one of:

- `bf` — Blowfish
- `aes` — AES (Rijndael-128, -192 or -256)

and *mode* is one of:

- `cbc` — next block depends on previous (default)
- `ecb` — each block is encrypted separately (for testing only)

and *padding* is one of:

- `pkcs` — data may be any length (default)
- `none` — data must be multiple of cipher block size

So, for example, these are equivalent:

```
encrypt(data, 'fooz', 'bf')
encrypt(data, 'fooz', 'bf-cbc/pad:pkcs')
```

In `encrypt_iv` and `decrypt_iv`, the *iv* parameter is the initial value for the CBC mode; it is ignored for ECB. It is clipped or padded with zeroes if not exactly block size. It defaults to all zeroes in the functions without this parameter.

F.39.5. Random-Data Functions

`gen_random_bytes(count integer)` returns `bytea`

Returns *count* cryptographically strong random bytes. At most 1024 bytes can be extracted at a time. This is to avoid draining the randomness generator pool.

`gen_random_uuid()` returns `uuid`

Returns a version 4 (random) UUID. (Obsolete, this function internally calls the [core function](#) of the same name.)

F.39.6. Notes

F.39.6.1. Configuration

`pgcrypto` configures itself according to the findings of the main Postgres Pro `configure` script. The options that affect it are `--with-zlib` and `--with-ssl=openssl`.

When compiled with `zlib`, PGP encryption functions are able to compress data before encrypting.

`pgcrypto` requires `OpenSSL`. Otherwise, it will not be built or installed.

When compiled against `OpenSSL 3.0.0` and later versions, the legacy provider must be activated in the `openssl.cnf` configuration file in order to use older ciphers like DES or Blowfish.

F.39.6.2. NULL Handling

As is standard in SQL, all functions return `NULL`, if any of the arguments are `NULL`. This may create security risks on careless usage.

F.39.6.3. Security Limitations

All `pgcrypto` functions run inside the database server. That means that all the data and passwords move between `pgcrypto` and client applications in clear text. Thus you must:

1. Connect locally or use SSL connections.
2. Trust both system and database administrator.

If you cannot, then better do crypto inside client application.

The implementation does not resist *side-channel attacks*. For example, the time required for a `pgcrypto` decryption function to complete varies among ciphertexts of a given size.

F.39.7. Author

Marko Kreen <markokr@gmail.com>

`pgcrypto` uses code from the following sources:

Algorithm	Author	Source origin
DES crypt	David Burren and others	FreeBSD libcrypt
MD5 crypt	Poul-Henning Kamp	FreeBSD libcrypt
Blowfish crypt	Solar Designer	www.openwall.com

F.40. pg_freespacemap — examine the free space map

The `pg_freespacemap` module provides a means for examining the [free space map](#) (FSM). It provides a function called `pg_freespace`, or two overloaded functions, to be precise. The functions show the value recorded in the free space map for a given page, or for all pages in the relation.

By default use is restricted to superusers and roles with privileges of the `pg_stat_scan_tables` role. Access may be granted to others using `GRANT`.

F.40.1. Functions

`pg_freespace(rel regclass IN, blkno bigint IN) returns int2`

Returns the amount of free space on the page of the relation, specified by `blkno`, according to the FSM.

`pg_freespace(rel regclass IN, blkno OUT bigint, avail OUT int2)`

Displays the amount of free space on each page of the relation, according to the FSM. A set of (`blkno` `bigint`, `avail` `int2`) tuples is returned, one tuple for each page in the relation.

The values stored in the free space map are not exact. They're rounded to precision of 1/256th of `BLCKSZ` (32 bytes with default `BLCKSZ`), and they're not kept fully up-to-date as tuples are inserted and updated.

For indexes, what is tracked is entirely-unused pages, rather than free space within pages. Therefore, the values are not meaningful, just whether a page is in-use or empty.

F.40.2. Sample Output

```
postgres=# SELECT * FROM pg_freespace('foo');
```

blkno	avail
0	0
1	0
2	0
3	32
4	704
5	704
6	704
7	1216
8	704
9	704
10	704
11	704
12	704
13	704
14	704
15	704
16	704
17	704
18	704
19	3648

(20 rows)

```
postgres=# SELECT * FROM pg_freespace('foo', 7);
```

pg_freespace
1216

(1 row)

Original version by Mark Kirkwood <markir@paradise.net.nz>. Rewritten in version 8.4 to suit new FSM implementation by Heikki Linnakangas <heikki@enterprisedb.com>

F.41. pg_pathman — an optimized partitioning solution for large and distributed databases

Important

Starting from Postgres Pro 12, using `pg_pathman` is not recommended. Use vanilla declarative partitioning instead, as described in [Section 5.11](#).

The `pg_pathman` is a Postgres Pro extension that provides an optimized partitioning solution for large and distributed databases. Using `pg_pathman`, you can:

- Partition large databases without downtime.
- Speed up query execution for partitioned tables.
- Manage existing partitions and add new partitions on the fly.
- Add foreign tables as partitions.
- Join partitioned tables for read and write operations.

The extension is compatible with Postgres Pro 9.5 or higher.

F.41.1. Installation and Setup

The `pg_pathman` extension is included into the Postgres Pro. Once you have Postgres Pro installed, complete the following steps to enable `pg_pathman`:

1. Add `pg_pathman` to the `shared_preload_libraries` variable in the `postgresql.conf` file:

```
shared_preload_libraries = 'pg_pathman'
```

Important

`pg_pathman` may have conflicts with other extensions that use the same hook functions. For example, `pg_pathman` may interfere with the `pg_stat_statements` extension as they both use `ProcessUtility_hook`. To avoid such issues, `pg_pathman` must always be the last in the list of libraries: `shared_preload_libraries = 'pg_stat_statements, pg_pathman'`

2. Restart the Postgres Pro instance for the settings to take effect.
3. Create the `pg_pathman` extension as follows:

```
CREATE SCHEMA pathman;  
GRANT USAGE ON SCHEMA pathman TO PUBLIC;  
CREATE EXTENSION pg_pathman WITH SCHEMA pathman;
```

Important

To ensure that your calls to `pg_pathman`'s functions are always secure against `search_path`-based attacks (see [CREATE EXTENSION](#) for details), install it only into a clean schema where nobody except superusers has the `CREATE` privilege for database objects.

Once `pg_pathman` is enabled, you can start partitioning tables.

Note

During installation, `pg_pathman` creates a few RLS policies to restrict access to its own tables. Postgres Pro core, however, does not support dump/restore of databases where extensions issuing

Additional Supplied Modules
and Extensions Shipped in
postgrespro-std-16-contrib

CREATE POLICY statements are installed. Therefore, when restoring a dump of a database where `pg_pathman` is installed, you will get error messages such as:

```
ERROR: policy "allow_select" for table "pathman_config" already exists
```

Ignore them since they do not affect whether the data being restored is complete.

Tip

You can also build `pg_pathman` from source code by executing the following command in the `pg_pathman` directory:

```
make install USE_PGXS=1
```

When this operation is complete, follow the steps described above to complete the setup.

In addition, do not forget to set the `PG_CONFIG` variable if you want to test `pg_pathman` on a custom build of Postgres Pro. For details, see [Building and Installing PostgreSQL Extension Modules](#).

You can toggle `pg_pathman` or its specific custom nodes on and off using GUC variables. For details, see [Section F.41.5.1](#).

If you want to permanently disable `pg_pathman` for a previously partitioned table, use the `disable_pathman_for()` function:

```
SELECT disable_pathman_for('range_rel');
```

All sections and data will remain unchanged and will be handled by the standard Postgres Pro inheritance mechanism.

F.41.1.1. Updating `pg_pathman`

If you already have a previous version of `pg_pathman` installed, complete the following steps to upgrade to a newer version:

1. Install Postgres Pro.
2. Restart your Postgres Pro cluster.
3. If you are running a previous major version of `pg_pathman` (the second digit in the version number is different), complete the update as follows:

```
ALTER EXTENSION pg_pathman UPDATE TO version;  
SET pg_pathman.enable = t;
```

where *version* is the `pg_pathman` major version number, such as 1.5.

You can check the current `pg_pathman` version by running the `pathman_version()` function.

F.41.2. Usage

[Choosing Partitioning Strategies](#)

[Running Non-Blocking Data Migration](#)

[Partitioning by a Single Expression](#)

[Partitioning by Composite Key](#)

[Running Multilevel Partitioning](#)

[Managing Partitions](#)

As your database grows, indexing mechanisms may become inefficient and cause high latency as you run queries. To improve performance, ensure scalability, and optimize database administration processes you can use partitioning — splitting a large table into smaller pieces, with each row moved to a single partition according to the partitioning key.

Traditionally, Postgres Pro has supported partitioning via table inheritance, with each partition created as a child table with a CHECK constraint. In Postgres Pro 10, support for [declarative partitioning](#) was added, which also relies on inheritance. With these approaches, the query planner has to perform an exhaustive search and check constraints on each partition to build a query plan, which may slow down queries for tables with a large number of partitions. The `pg_pathman` extension uses an optimized planning algorithms and partitioning functions based on the internal structure of the partitioned tables, which allows to achieve better performance results. For details on `pg_pathman` implementation specifics, see [Section F.41.4](#).

F.41.2.1. Choosing Partitioning Strategies

The `pg_pathman` extension supports the following partitioning strategies:

- Hash — maps rows to partitions using a generic hash function. Choose this strategy if most of your queries will be of the exact-match type.
- Range — maps rows to partitions based on partitioning key ranges assigned to each partition. Choose this strategy if your database contains numeric data that you are likely to query or manage by ranges. For example, you may want to query historical data by years, or review experiment results by specific numeric ranges. To achieve performance gains, `pg_pathman` uses the binary search algorithm.

By default, `pg_pathman` migrates all data from the parent table to the newly created partitions at once (*blocking partitioning*). This approach enables you to restructure the table in a single transaction, but may cause downtime if you have a lot of data. If it is critical to avoid downtime, you can use *concurrent partitioning*. In this case, `pg_pathman` writes all the updates to the newly created partitions, but keeps the original data in the parent table until you explicitly migrate it. This enables you to partition large databases without downtime, as you can choose convenient time for migration and copy data in small batches without blocking other transactions. For details on concurrent partitioning, see [Section F.41.2.2](#).

F.41.2.1.1. Setting up Hash Partitioning

To perform hash partitioning with `pg_pathman`, run the `create_hash_partitions()` function:

```
create_hash_partitions(parent_relid      REGCLASS,  
                      expression        TEXT,  
                      partitions_count  INTEGER,  
                      partition_data    BOOLEAN DEFAULT TRUE,  
                      partition_names   TEXT[]  DEFAULT NULL,  
                      tablespaces      TEXT[]  DEFAULT NULL)
```

The `pg_pathman` module creates the specified number of partitions based on the hash function. Optionally, you can specify partition names and tablespaces by setting `partition_names` and `tablespaces` options, respectively.

You cannot add or remove partitions after the parent table is split. If required, you can replace the specified partition with another table:

```
replace_hash_partition(old_partition    REGCLASS,  
                      new_partition    REGCLASS,  
                      lock_parent      BOOL DEFAULT TRUE);
```

When set to `true`, `lock_parent` parameter will prevent any `INSERT/UPDATE/ALTER TABLE` queries to parent table.

If you omit the optional `partition_data` parameter or set it to `true`, all the data from the parent table gets migrated to partitions. The `pg_pathman` module blocks the table for other transactions until data

migration completes. To avoid downtime, you can set the `partition_data` parameter to `false` and later use the `partition_table_concurrently()` function to migrate your data to partitions without blocking other queries. For details, see the [Section F.41.2.2](#).

F.41.2.1.2. Setting up Range Partitioning

The `pg_pathman` module provides the `create_range_partitions()` for range partitioning. This function creates partitions based on the specified interval and the initial partitioning key value. New partitions are created automatically when you insert data outside of the already covered range.

```
create_range_partitions(parent_relid    REGCLASS,  
                        expression      TEXT,  
                        start_value     ANYELEMENT,  
                        p_interval      ANYELEMENT | INTERVAL,  
                        p_count         INTEGER DEFAULT NULL,  
                        partition_data  BOOLEAN DEFAULT TRUE)
```

The `pg_pathman` module creates partitions based on the specified parameters. If you omit the optional `p_count` parameter, `pg_pathman` calculates the required number of partitions based on the specified start value and interval. If you insert new data outside of the existing partition range, `pg_pathman` creates new partitions automatically, keeping the specified interval. This approach ensures that all partitions are of the same size, which can improve query performance and facilitate database management.

Alternatively, you can specify an array defining the bounds of partitions to be created using the `bounds` parameter:

```
create_range_partitions(parent_relid    REGCLASS,  
                        expression      TEXT,  
                        bounds           ANYARRAY,  
                        partition_names  TEXT[] DEFAULT NULL,  
                        tablespaces      TEXT[] DEFAULT NULL,  
                        partition_data  BOOLEAN DEFAULT TRUE)
```

If required, you can also use [partition management functions](#) to add partitions manually. For example, if there is a gap between the created partitions, `pg_pathman` cannot fill it with a new partition in an automated mode.

By default, all the data from the parent table gets migrated to the specified number of partitions. The `pg_pathman` module blocks the table for other transactions until data migration completes. To avoid downtime, you can set the `partition_data` parameter to `false` and later use the `partition_table_concurrently()` function to migrate your data to partitions without blocking other queries. For details, see the [Section F.41.2.2](#).

F.41.2.2. Running Non-Blocking Data Migration

If it is critical to avoid downtime, you can perform concurrent partitioning by setting the `partition_data` parameter of the partitioning function to `false`. In this case, `pg_pathman` creates empty partitions, keeping all the original data in the parent table. At the same time, all the database updates are written to the newly created partitions. You can later migrate the original data to partitions without blocking other queries using the `partition_table_concurrently()` function:

```
partition_table_concurrently(relation    REGCLASS,  
                             batch_size  INTEGER DEFAULT 1000,  
                             sleep_time  FLOAT8 DEFAULT 1.0)
```

where:

- `relation` is the parent table.
- `batch_size` is the number of rows to copy from the parent table to partitions at a time. You can set this parameter to any integer value from 1 to 10000.
- `sleep_time` is the time interval between migration attempts, in seconds.

The `pg_pathman` module starts a background worker to move the data from the parent table to partitions in small batches of the specified `batch_size`. If one or more rows in the batch are locked by other queries, `pg_pathman` waits for the specified `sleep_time` and tries again, up to 60 times. You can monitor the migration process in the `pathman_concurrent_part_tasks` view that shows the number of rows migrated so far:

```
[user]postgres: select * from pathman_concurrent_part_tasks ;
userid | pid  | dbid | relid | processed | status
-----+-----+-----+-----+-----+-----
user   | 20012 | 12413 | test  | 334000    | working
(1 row)
```

If you need to stop data migration, run the `stop_concurrent_part_task()` function at any time:

```
SELECT stop_concurrent_part_task(relation REGCLASS);
```

`pg_pathman` completes the migration of the current batch and terminates the migration process.

Tip

When `pg_pathman` migrates all the data from the parent table, you can exclude the parent table from the query plan. See the `set_enable_parent()` function description for details.

F.41.2.3. Partitioning by a Single Expression

For both range and hash partitioning strategies, `pg_pathman` supports partitioning by expression that returns a single scalar value. The partitioning expression can reference a table column, as well as calculate the partitioning key based on one or more column values.

Tip

If you would like to partition a table by a tuple, see [Section F.41.2.4](#).

To partition a table by expression, use `pg_pathman` [partitioning functions](#). The partitioning expression must satisfy the following conditions:

- Expression must reference at least one column of the partitioned table.
- All referenced columns must be marked as `NOT NULL`.
- Expression cannot reference system attributes, such as `oid`, `xmin`, `xmax`, etc.
- Expression cannot include subqueries.
- All functions used by expression must be marked as `IMMUTABLE`.

As the expression can return a value of virtually any type, make sure to convert it to the type you need for partitioning.

To access a partition, you must use the exact expression used for partitioning. Otherwise, `pg_pathman` cannot optimize the query. You can view the partitioning expression for each partitioned table in the `pathman_config` table.

F.41.2.3.1. Examples

Suppose you have the `test` table that stores some `jsonb` data:

```
CREATE TABLE test(col jsonb NOT NULL);
INSERT INTO test
SELECT format('{ "key": %s, "date": "%s", "value": "%s"}',
              i, current_date, md5(i::text))::jsonb
FROM generate_series(1, 10000 * 10) as g(i);
```

To partition this data by range of the key value, you need to extract this value from the `jsonb` object and convert it to a numeric type, such as `bigint`:

```
SELECT create_range_partitions('test', '(col->>'key')::bigint', 1, 10000, 10);
```

`pg_pathman` splits the parent table into ten partitions, with each partition storing 10000 rows:

```
SELECT * FROM pathman_partition_list;
```

parent	partition	parttype	expr	range_min	range_max
test	test_1	2	((col ->> 'key')::text)::bigint	1	10001
test	test_2	2	((col ->> 'key')::text)::bigint	10001	20001
test	test_3	2	((col ->> 'key')::text)::bigint	20001	30001
test	test_4	2	((col ->> 'key')::text)::bigint	30001	40001
test	test_5	2	((col ->> 'key')::text)::bigint	40001	50001
test	test_6	2	((col ->> 'key')::text)::bigint	50001	60001
test	test_7	2	((col ->> 'key')::text)::bigint	60001	70001
test	test_8	2	((col ->> 'key')::text)::bigint	70001	80001
test	test_9	2	((col ->> 'key')::text)::bigint	80001	90001
test	test_10	2	((col ->> 'key')::text)::bigint	90001	100001

(10 rows)

F.41.2.4. Partitioning by Composite Key

Using `pg_pathman`, you can also perform range partitioning by composite key. A composite key consists of two or more comma-separated values, which can be columns or expressions extracting the values from the table. The expressions defining the composite key must satisfy the conditions described in [Section F.41.2.3](#).

Although `pg_pathman` does not support automatic partition creation by composite key, you can add partitions using the `add_range_partition()` function. A typical workflow is as follows:

1. Enable automatic partition naming for your table by running the `create_naming_sequence()` function.
2. Create a composite partitioning key.
3. Register a table you are going to partition with `pg_pathman` using the `add_to_pathman_config()` function.
4. Add a partition based on the defined composite partitioning key using the `add_range_partition()` function.

F.41.2.4.1. Examples

Suppose you have the `test` table that stores some temporal data:

```
CREATE TABLE test (logdate date NOT NULL, comment text);
```

To partition this data by month and year, you have to create a composite key:

```
CREATE TYPE test_key AS (year float8, month float8);
```

To enable automatic partition naming, run the `create_naming_sequence()` function passing the table name as an argument:

```
SELECT create_naming_sequence('test');
```

Register the `test` table with `pg_pathman`, specifying the partitioning key you are going to use:

```
SELECT add_to_pathman_config('test',
                             '( extract(year from logdate),
```

```
extract(month from logdate) )::test_key',  
NULL);
```

Create a partition that includes all the data in the range of ten years, starting from January of the current year:

```
SELECT add_range_partition('test',  
                           (extract(year from current_date), 1)::test_key,  
                           (extract(year from current_date + '10 years'::interval),  
                             1)::test_key);
```

F.41.2.5. Running Multilevel Partitioning

`pg_pathman` supports multilevel partitioning for both hash and range partitioning strategies. You can use partitioning strategies in any combination: a hash- or range-partitioned table can be further partitioned by both hash or range.

To split an existing partition into several child ones, use the regular `pg_pathman` partitioning functions as explained in [Section F.41.2.1](#), passing the name of the partition to be split as the *parent_relid* parameter. You can check the exact partition names in the [pathman_partition_list](#) view.

When opting for the range-range partitioning combination, you can either choose a different partitioning expression, or use the same expression as for the parent table. In the latter case, if the selected range is larger than that of the parent partition, only those child partitions that intersect with the parent range will be in use. Other child partitions will remain empty unless their parent is merged with an adjacent partition that covers at least a part of their range.

F.41.2.5.1. Examples

Suppose you have the `journal` table with some logs, which is partitioned by month:

```
-- create an empty table  
CREATE TABLE journal (  
  id      SERIAL,  
  dt      TIMESTAMP NOT NULL,  
  level   INTEGER,  
  msg     TEXT);  
  
-- generate some log data into the table  
INSERT INTO journal (dt, level, msg)  
SELECT g, random() * 6, md5(g::text)  
FROM generate_series('2015-01-01'::date, '2015-12-31'::date, '1 minute') as g;  
  
-- partition the table by range  
SELECT create_range_partitions('journal', 'dt', '2015-01-01'::date, '1  
  month'::interval);
```

If having smaller partitions makes more sense at some point, you can further split the partitions by hash or range. For example, to split the `journal_1` partition into subpartitions by day, run:

```
SELECT create_range_partitions('journal_1', 'dt', '2015-01-01'::date, '1  
  day'::interval);
```

Similarly, you can use hash partitioning to create child partitions. For example, split the `journal_2` partition into five partitions by hash using the `id` column as the partitioning key:

```
SELECT create_hash_partitions('journal_2', 'id', '5');
```

F.41.2.6. Managing Partitions

`pg_pathman` provides multiple functions for easy partition management. For details, see [Section F.41.5.3.4](#).

F.41.3. Examples

F.41.3.1. Common Tips

- You can add `partition` column containing the names of the underlying partitions using the system attribute called `tableoid`:

```
SELECT tableoid::regclass AS partition, * FROM partitioned_table;
```

- Though indices on a parent table are not particularly useful (since the parent table is supposed to be empty), they act as prototypes for indices on partitions. For each index on the parent table, `pg_pathman` creates a similar index on each partition.
- All running concurrent partitioning tasks can be listed using the `pathman_concurrent_part_tasks` view:

```
SELECT * FROM pathman_concurrent_part_tasks;
userid | pid | dbid | relid | processed | status
-----+-----+-----+-----+-----+-----
user   | 7367 | 16384 | test  | 472000    | working
(1 row)
```

- The `pathman_partition_list` in conjunction with `drop_range_partition()` can be used to drop range partitions in a more flexible way compared to `DROP TABLE`:

```
SELECT drop_range_partition(partition, false) /* move data to parent */
FROM pathman_partition_list
WHERE parent = 'part_test'::regclass AND range_min::int < 500;
NOTICE:  1 rows copied from part_test_11
NOTICE: 100 rows copied from part_test_1
NOTICE: 100 rows copied from part_test_2
drop_range_partition
-----
dummy_test_11
dummy_test_1
dummy_test_2
(3 rows)
```

- You can turn foreign tables into partitions using the `attach_range_partition()` function. Rows that were meant to be inserted into the parent will be redirected to foreign partitions using `PartitionFilter`. By default, it is only allowed to insert rows into partitions provided by `postgres_fdw`. This setting is controlled by the `pg_pathman.insert_into_fdw` variable. You must have superuser rights to change this setting.

F.41.3.2. Hash Partitioning

Consider an example of hash partitioning. First create a table with an integer column:

```
CREATE TABLE items (
id          SERIAL PRIMARY KEY,
name        TEXT,
code        BIGINT);

INSERT INTO items (id, name, code)
SELECT g, md5(g::text), random() * 100000
FROM generate_series(1, 100000) as g;
```

Now run the `create_hash_partitions()` function with appropriate arguments:

```
SELECT create_hash_partitions('items', 'id', 100);
```

This will create new partitions and move the data from the parent table to partitions.

Here is an example of the query performing filtering by partitioning key:

```
SELECT * FROM items WHERE id = 1234;
 id | name | code
----+-----+-----
1234 | 81dc9bdb52d04dc20036dbd8313ed055 | 1855
(1 row)
```

```
EXPLAIN SELECT * FROM items WHERE id = 1234;
QUERY PLAN
```

```
-----
Append  (cost=0.28..8.29 rows=0 width=0)
->  Index Scan using items_34_pkey on items_34  (cost=0.28..8.29 rows=0 width=0)
    Index Cond: (id = 1234)
```

Notice that the Append node contains only one child scan, which corresponds to the WHERE clause.

Important

Pay attention to the fact that `pg_pathman` excludes the parent table from the query plan.

To access the parent table, use the ONLY modifier:

```
EXPLAIN SELECT * FROM ONLY items;
QUERY PLAN
-----
Seq Scan on items  (cost=0.00..0.00 rows=1 width=45)
```

F.41.3.3. Range Partitioning

Consider an example of range partitioning. Let's create a table containing some dummy logs:

```
CREATE TABLE journal (
id      SERIAL,
dt      TIMESTAMP NOT NULL,
level   INTEGER,
msg     TEXT);

-- similar index will also be created for each partition
CREATE INDEX ON journal(dt);

-- generate some data
INSERT INTO journal (dt, level, msg)
SELECT g, random() * 6, md5(g::text)
FROM generate_series('2015-01-01'::date, '2015-12-31'::date, '1 minute') as g;
```

Run the `create_range_partitions()` function to create partitions so that each partition would contain the data for one day:

```
SELECT create_range_partitions('journal', 'dt', '2015-01-01'::date, '1 day'::interval);
```

It will create 364 partitions and move the data from the parent table to partitions.

New partitions are appended automatically by insert trigger, but it can be done manually with the following functions:

```
-- add new partition with specified range
SELECT add_range_partition('journal', '2016-01-01'::date, '2016-01-07'::date);
```

```
-- append new partition with default range
SELECT append_range_partition('journal');
```

The first one creates a partition with specified range. The second one creates a partition with default interval and appends it to the partition list. It is also possible to attach an existing table as partition. For example, we may want to attach an archive table (or even foreign table from another server) for some outdated data:

```
CREATE FOREIGN TABLE journal_archive (
id      INTEGER NOT NULL,
dt      TIMESTAMP NOT NULL,
level   INTEGER,
msg     TEXT)
SERVER archive_server;
```

```
SELECT attach_range_partition('journal', 'journal_archive', '2014-01-01'::date,
'2015-01-01'::date);
```

Important

The attached table must have the same columns as the partitioned table, except for the dropped columns. The attached columns must have the same type, collation, and NOT NULL settings as the original columns.

To merge two adjacent partitions, use the `merge_range_partitions()` function:

```
SELECT merge_range_partitions('journal_archive', 'journal_1');
```

To split partition by value, use the `split_range_partition()` function:

```
SELECT split_range_partition('journal_366', '2016-01-03'::date);
```

To detach partition, use the `detach_range_partition()` function:

```
SELECT detach_range_partition('journal_archive');
```

Here is an example of the query performing filtering by partitioning key:

```
SELECT * FROM journal WHERE dt >= '2015-06-01' AND dt < '2015-06-03';
id      |          dt          | level |          msg
-----+-----+-----+-----
217441  | 2015-06-01 00:00:00 |     2 | 15053892d993ce19f580a128f87e3dbf
217442  | 2015-06-01 00:01:00 |     1 | 3a7c46f18a952d62ce5418ac2056010c
217443  | 2015-06-01 00:02:00 |     0 | 92c8de8f82faf0b139a3d99f2792311d
...
(2880 rows)
```

```
EXPLAIN SELECT * FROM journal WHERE dt >= '2015-06-01' AND dt < '2015-06-03';
QUERY PLAN
```

```
-----
Append  (cost=0.00..58.80 rows=0 width=0)
->  Seq Scan on journal_152  (cost=0.00..29.40 rows=0 width=0)
->  Seq Scan on journal_153  (cost=0.00..29.40 rows=0 width=0)
(3 rows)
```

F.41.4. Internals

`pg_pathman` stores partitioning configuration in the `pathman_config` table; each row contains a single entry for a partitioned table (relation name, partitioning column and its type). During the initialization

stage the `pg_pathman` module caches some information about child partitions in the shared memory, which is used later for plan construction. Before a `SELECT` query is executed, `pg_pathman` traverses the condition tree in search of expressions like:

```
VARIABLE OP CONST
```

where `VARIABLE` is a partitioning key, `OP` is a comparison operator (supported operators are `=`, `<`, `<=`, `>`, `>=`), `CONST` is a scalar value. For example:

```
WHERE id = 150
```

Based on the partitioning type and condition's operator, `pg_pathman` searches for the corresponding partitions and builds the plan.

F.41.4.1. Custom Plan Nodes

`pg_pathman` provides a couple of *custom plan nodes* which aim to reduce execution time, namely:

- `RuntimeAppend` (overrides `Append` plan node)
- `RuntimeMergeAppend` (overrides `MergeAppend` plan node)
- `PartitionFilter` (drop-in replacement for `INSERT` triggers)
- `PartitionRouter` for cross-partition `UPDATE` queries instead of triggers

`PartitionFilter` acts as a *proxy node* for `INSERT`'s child scan, which means it can redirect output tuples to the corresponding partition:

```
EXPLAIN (COSTS OFF)
INSERT INTO partitioned_table
SELECT generate_series(1, 10), random();
      QUERY PLAN
-----
Insert on partitioned_table
-> Custom Scan (PartitionFilter)
    -> Subquery Scan on "*SELECT*"
        -> Result

(4 rows)
```

`PartitionRouter` is another proxy node used in conjunction with `PartitionFilter` to enable cross-partition `UPDATE` operations, for example, when you update any column of a partitioning key.

Important

The `PartitionRouter` node transforms cross-partition `UPDATE` commands into `DELETE + INSERT`. On Postgres Pro versions prior to 11, this operation is unsafe as `pg_pathman` cannot determine whether the updated row has been deleted or moved to another partition.

By default, `PartitionRouter` is disabled to avoid undesirable side effects. To enable this node, set the `pg_pathman.enable_partitionrouter` to on.

```
EXPLAIN (COSTS OFF)
UPDATE partitioned_table
SET value = value + 1 WHERE value = 2;
      QUERY PLAN
-----
Update on partitioned_table_0
-> Custom Scan (PartitionRouter)
    -> Custom Scan (PartitionFilter)
        -> Seq Scan on partitioned_table_0
            Filter: (value = 2)
```

(5 rows)

RuntimeAppend and RuntimeMergeAppend have much in common: they come in handy in a case when WHERE condition takes form of:

VARIABLE OP PARAM

This kind of expressions can no longer be optimized at planning time since the parameter's value is not known until the execution stage takes place. The problem can be solved by embedding the *WHERE condition analysis routine* into the original Append's code, thus making it pick only required scans out of a whole bunch of planned partition scans. This effectively boils down to creation of a custom node capable of performing such a check.

There are at least several cases that demonstrate usefulness of these nodes:

```
/* create table we're going to partition */
CREATE TABLE partitioned_table(id INT NOT NULL, payload REAL);

/* insert some data */
INSERT INTO partitioned_table
SELECT generate_series(1, 1000), random();

/* perform partitioning */
SELECT create_hash_partitions('partitioned_table', 'id', 100);

/* create ordinary table */
CREATE TABLE some_table AS SELECT generate_series(1, 100) AS VAL;
```

- id = (select ... limit 1)

```
EXPLAIN (COSTS OFF, ANALYZE) SELECT * FROM partitioned_table
WHERE id = (SELECT * FROM some_table LIMIT 1);
```

QUERY PLAN

```
-----
Custom Scan (RuntimeAppend) (actual time=0.030..0.033 rows=1 loops=1)
  InitPlan 1 (returns $0)
    -> Limit (actual time=0.011..0.011 rows=1 loops=1)
          -> Seq Scan on some_table (actual time=0.010..0.010 rows=1 loops=1)
    -> Seq Scan on partitioned_table_70 partitioned_table (actual time=0.004..0.006
rows=1 loops=1)
      Filter: (id = $0)
      Rows Removed by Filter: 9
Planning time: 1.131 ms
Execution time: 0.075 ms
(9 rows)
```

```
/* disable RuntimeAppend node */
SET pg_pathman.enable_runtimeappend = f;
```

```
EXPLAIN (COSTS OFF, ANALYZE) SELECT * FROM partitioned_table
WHERE id = (SELECT * FROM some_table LIMIT 1);
```

QUERY PLAN

```
-----
Append (actual time=0.196..0.274 rows=1 loops=1)
  InitPlan 1 (returns $0)
    -> Limit (actual time=0.005..0.005 rows=1 loops=1)
          -> Seq Scan on some_table (actual time=0.003..0.003 rows=1 loops=1)
    -> Seq Scan on partitioned_table_0 (actual time=0.014..0.014 rows=0 loops=1)
      Filter: (id = $0)
      Rows Removed by Filter: 6
```

Additional Supplied Modules
and Extensions Shipped in
postgrespro-std-16-contrib

```
-> Seq Scan on partitioned_table_1 (actual time=0.003..0.003 rows=0 loops=1)

      -> Limit (actual time=0.005..0.006 rows=4 loops=1)
          -> Seq Scan on some_table (actual time=0.003..0.004 rows=4 loops=1)
Planning time: 2.169 ms
Execution time: 2.059 ms
(110 rows)
```

- NestLoop **involving a partitioned table**, which is omitted since it's occasionally shown above.

To learn more about custom nodes, see Alexander Korotkov's [blog](#).

F.41.5. Reference

F.41.5.1. GUC Variables

There are several user-accessible [GUC](#) variables designed to toggle `pg_pathman` or its specific custom nodes on and off.

- `pg_pathman.enable` — enable/disable the `pg_pathman` module.

Default: on

- `pg_pathman.enable_runtimeappend` — toggle the `RuntimeAppend` custom node on/off.

Default: on

- `pg_pathman.enable_runtimemergeappend` — toggle the `RuntimeMergeAppend` custom node on/off.

Default: on

- `pg_pathman.enable_partitionfilter` — toggle the `PartitionFilter` custom node on/off to enable/disable cross-partition `INSERT` operations.

Default: on

- `pg_pathman.enable_partitionrouter` — toggle the `PartitionRouter` custom node on/off to enable/disable cross-partition `UPDATE` operations.

Default: off

- `pg_pathman.enable_auto_partition` — toggle automatic partition creation on/off (per session).

Default: on

- `pg_pathman.enable_bounds_cache` — toggle bounds cache on/off.

Default: on

- `pg_pathman.insert_into_fdw` — allow `INSERT` operations into various foreign-data wrappers. Possible values: `disabled`, `postgres`, and `any_fdw`.

Default: `postgres`

- `pg_pathman.override_copy` — toggle `COPY` statement hooking on/off.

Default: on

F.41.5.2. Views and Tables

F.41.5.2.1. `pathman_config`

This table stores the list of partitioned tables. This is the main configuration storage.

```
CREATE TABLE IF NOT EXISTS pathman_config (  
    partrel          REGCLASS NOT NULL PRIMARY KEY,  
    attname          TEXT NOT NULL,  
    parttype         INTEGER NOT NULL,  
    range_interval   TEXT);
```

F.41.5.2.2. `pathman_config_params`

This table stores optional parameters that override standard `pg_pathman` behavior.

```
CREATE TABLE IF NOT EXISTS pathman_config_params (  
    partrel          REGCLASS NOT NULL PRIMARY KEY,  
    enable_parent    BOOLEAN NOT NULL DEFAULT TRUE,  
    auto             BOOLEAN NOT NULL DEFAULT TRUE,  
    init_callback    REGPROCEDURE NOT NULL DEFAULT 0,  
    spawn_using_bgw  BOOLEAN NOT NULL DEFAULT FALSE);
```

F.41.5.2.3. pathman_concurrent_part_tasks

This view lists all currently running concurrent partitioning tasks.

```
-- helper SRF function
CREATE OR REPLACE FUNCTION show_concurrent_part_tasks()
RETURNS TABLE (
    userid      REGROLE,
    pid         INT,
    dbid        OID,
    relid       REGCLASS,
    processed   INT,
    status      TEXT)
AS 'pg_pathman', 'show_concurrent_part_tasks_internal'
LANGUAGE C STRICT;

CREATE OR REPLACE VIEW pathman_concurrent_part_tasks
AS SELECT * FROM show_concurrent_part_tasks();
```

F.41.5.2.4. pathman_partition_list

This view lists all existing partitions, as well as their parents and range boundaries (NULL for hash partitions).

```
-- helper SRF function
CREATE OR REPLACE FUNCTION show_partition_list()
RETURNS TABLE (
    parent      REGCLASS,
    partition   REGCLASS,
    parttype    INT4,
    expr        TEXT,
    range_min   TEXT,
    range_max   TEXT)
AS 'pg_pathman', 'show_partition_list_internal'
LANGUAGE C STRICT;

CREATE OR REPLACE VIEW pathman_partition_list
AS SELECT * FROM show_partition_list();
```

F.41.5.3. Functions

F.41.5.3.1. Partitioning Functions

```
create_hash_partitions(parent_relid      REGCLASS,
                      expression        TEXT,
                      partitions_count  INTEGER,
                      partition_data    BOOLEAN DEFAULT TRUE,
                      partition_names   TEXT[]  DEFAULT NULL,
                      tablespaces      TEXT[]  DEFAULT NULL)
```

Performs hash partitioning for relation by integer key expression. The `partitions_count` parameter specifies the number of partitions to create; it cannot be changed afterwards. If `partition_data` is `true`, all the data will be automatically migrated from the parent table to partitions. Note that data migration may take a while to finish and the table will be locked until transaction commits. See `partition_table_concurrently()` for a lock-free way to migrate data. Partition creation callback is invoked for each partition if set beforehand (see `set_init_callback()`).

```
create_range_partitions(relation        REGCLASS,
                      expression        TEXT,
                      start_value       ANYELEMENT,
                      p_interval        ANYELEMENT,
```

**Additional Supplied Modules
and Extensions Shipped in
postgrespro-std-16-contrib**

p_count	INTEGER DEFAULT NULL,
partition_data	BOOLEAN DEFAULT TRUE)
create_range_partitions(relation	REGCLASS,
expression	TEXT,
start_value	ANYELEMENT,
p_interval	INTERVAL,
p_count	INTEGER DEFAULT NULL,
partition_data	BOOLEAN DEFAULT TRUE)
create_range_partitions(relation	REGCLASS,
expression	TEXT,
bounds	ANYARRAY,
partition_names	TEXT[] DEFAULT NULL,
tablespaces	TEXT[] DEFAULT NULL,
partition_data	BOOLEAN DEFAULT TRUE)

Performs range partitioning for `relation` by partitioning key defined by `expression`. The `start_value` argument specifies the initial value, `p_interval` sets the default range for automatically created partitions or partitions created with `append_range_partition()` or `prepend_range_partition()`. If `p_interval` is set to `NULL`, automatic partition creation is disabled. `p_count` is the number of premade partitions. If `p_count` is not set, than `pg_pathman` tries to determine the number of partitions based on the `expression` value. The `bounds` array defines the bounds for partitions to be created. You can build this array using the `generate_range_bounds()` function. Partition creation callback is invoked for each partition if set beforehand.

F.41.5.3.2. Data Migration Functions

```
partition_table_concurrently(relation REGCLASS,
                             batch_size INTEGER DEFAULT 1000,
                             sleep_time FLOAT8 DEFAULT 1.0)
```

Starts a background worker to move data from parent table to partitions. The worker utilizes short transactions to copy small batches of data (up to 10K rows per transaction) and thus doesn't significantly interfere with user's activity.

```
stop_concurrent_part_task(relation REGCLASS)
```

Stops a background worker performing a concurrent partitioning task. Note: worker will exit after it finishes relocating a current batch.

F.41.5.3.3. Triggers

Triggers are no longer required for `INSERT` and cross-partition `UPDATE` operations. However, user-supplied triggers are supported:

- Each inserted row results in execution of BEFORE/AFTER `INSERT` trigger functions of a corresponding partition.
- Each updated row results in execution of BEFORE/AFTER `UPDATE` trigger functions of a corresponding partition.
- Each moved row (cross-partition update) results in execution of BEFORE `UPDATE` + BEFORE/AFTER `DELETE` + BEFORE/AFTER `INSERT` trigger functions of corresponding partitions.

F.41.5.3.4. Partition Management Functions

```
replace_hash_partition(old_partition REGCLASS,
                       new_partition REGCLASS,
                       lock_parent BOOLEAN DEFAULT TRUE)
```

Replaces the specified partition of hash-partitioned table with another table. When set to `true`, the `lock_parent` parameter prevents any `INSERT/UPDATE/ALTER TABLE` queries to the parent table.

Additional Supplied Modules
and Extensions Shipped in
postgrespro-std-16-contrib

```
split_range_partition(partition_relid REGCLASS,  
                      split_value    ANYELEMENT,  
                      partition_name  TEXT DEFAULT NULL,  
                      tablespace     TEXT DEFAULT NULL)
```

Split range partition in two by value, with the specified value included into the second partition. Partition creation callback is invoked for a new partition if available.

```
merge_range_partitions(variadic partitions REGCLASS[])
```

Merge several adjacent range partitions. Partitions are automatically ordered by increasing bounds. All the data will be accumulated in the first partition, while other merged partitions are removed. If the remaining partition has any child partitions, new child partitions for the merged data will be created as required using the same partitioning expression.

```
append_range_partition(parent_relid  REGCLASS,  
                       partition_name TEXT DEFAULT NULL,  
                       tablespace    TEXT DEFAULT NULL)
```

Append new range partition with `pathman_config.range_interval` as interval.

```
prepend_range_partition(parent_relid  REGCLASS,  
                        partition_name TEXT DEFAULT NULL,  
                        tablespace    TEXT DEFAULT NULL)
```

Prepend new range partition with `pathman_config.range_interval` as interval.

```
add_range_partition(parent_relid  REGCLASS,  
                    start_value   ANYELEMENT,  
                    end_value     ANYELEMENT,  
                    partition_name TEXT DEFAULT NULL,  
                    tablespace    TEXT DEFAULT NULL)
```

Create a new range partition for relation with the specified range bounds. If the `start_value` or the `end_value` is NULL, the corresponding range bound will be infinite.

```
drop_range_partition(partition_relid TEXT, delete_data BOOLEAN DEFAULT TRUE)
```

Drop range partition and all of its data if `delete_data` is true.

```
attach_range_partition(parent_relid  REGCLASS,  
                       partition_relid REGCLASS,  
                       start_value   ANYELEMENT,  
                       end_value     ANYELEMENT)
```

Attach partition to the existing range-partitioned relation. The attached table must have exactly the same structure as the parent table, including the dropped columns. Partition creation callback is invoked if set (see [Section F.41.5.2.2](#)).

```
detach_range_partition(partition_relid REGCLASS)
```

Detach partition from the existing range-partitioned relation.

```
disable_pathman_for(parent_relid REGCLASS)
```

Permanently disable `pg_pathman` partitioning mechanism for the specified parent table and remove the insert trigger if it exists. All partitions and data remain unchanged.

```
drop_partitions(parent_relid REGCLASS,  
                delete_data  BOOLEAN DEFAULT FALSE)
```

Drop partitions of the parent table (both foreign and local relations). If `delete_data` is false, the data is copied to the parent table first. Default is false.

F.41.5.3.5. Additional Functions

`pathman_version()`

Returns the `pg_pathman` version number.

`set_interval(relation REGCLASS, value ANYELEMENT)`

Update range-partitioned table interval. Note that interval must not be negative and it must not be trivial, i.e. its value should be greater than zero for numeric types, at least 1 microsecond for `timestamp` and at least 1 day for `date`.

`set_enable_parent(relation REGCLASS, value BOOLEAN)`

Include/exclude parent table into/from query plan. In original Postgres Pro planner parent table is always included into query plan even if it's empty, which can lead to additional overhead. You can use `disable_parent()` if you are never going to use parent table as a storage. Default value depends on the `partition_data` parameter specified during initial partitioning with the `create_range_partitions()` function. If the `partition_data` parameter was `true`, then all data have already been migrated to partitions and the parent table is disabled. Otherwise, it is enabled.

`set_auto(relation REGCLASS, value BOOLEAN)`

Enable/disable auto partition propagation (only for range partitioning). It is enabled by default.

`set_init_callback(relation REGCLASS, callback REGPROCEDURE DEFAULT 0)`

Set partition creation callback to be invoked for each attached or created partition (both hash and range). If callback is marked with `SECURITY INVOKER`, it is executed with the privileges of the user who produced a statement that has led to creation of a new partition. For example:

```
INSERT INTO partitioned_table VALUES (-5)
```

The callback must have the following signature: `part_init_callback(args JSONB) RETURNS VOID`. Parameter `arg` consists of several fields whose presence depends on partitioning type:

```
/* Range-partitioned table abc (child abc_4) */
{
    "parent":    "abc",
    "parttype":  "2",
    "partition": "abc_4",
    "range_max": "401",
    "range_min": "301"
}

/* Hash-partitioned table abc (child abc_0) */
{
    "parent":    "abc",
    "parttype":  "1",
    "partition": "abc_0"
}
```

`set_spawn_using_bgw(relation REGCLASS, value BOOLEAN)`

When inserting new data beyond the partitioning range, use `SpawnPartitionsWorker` to create new partitions in a separate transaction.

`create_naming_sequence(parent_relid REGCLASS)`

Enable automatic partition naming for the specified `relation` table. You must run this function when partitioning this table by composite key.

Additional Supplied Modules
and Extensions Shipped in
postgrespro-std-16-contrib

```
add_to_pathman_config(parent_relid    REGCLASS,  
                      expression      TEXT,  
                      range_interval  TEXT)  
add_to_pathman_config(parent_relid    REGCLASS,  
                      expression      TEXT)
```

Register the specified relation table with `pg_pathman` to enable partitioning by the provided expression. For range partitioning, the `range_interval` argument is mandatory. You can set it to `NULL` if you are going to add partition manually.

```
generate_range_bounds(p_start    ANYELEMENT,  
                     p_interval  INTERVAL,  
                     p_count     INTEGER)
```

```
generate_range_bounds(p_start    ANYELEMENT,  
                     p_interval  ANYELEMENT,  
                     p_count     INTEGER)
```

Build the `bounds` array that defines the bounds for partitions to be created. You can pass this array as an argument to the `create_range_partitions()` function.

F.42. pg_proaudit — enables detailed logging of various security events

The `pg_proaudit` extension enables detailed logging of various security events.

`pg_proaudit` works in parallel with the standard PostgreSQL logging solutions (logging collector) and does not depend on them. Security event log of the `pg_proaudit` extension is stored separately from the server log. At the Postgres Pro Standard startup, `pg_proaudit` launches a special background process to log security events.

Logging rules are stored in the `pg_proaudit.conf` configuration file located in the cluster data directory (PGDATA). It is a text file that can be edited directly using operating system facilities. To modify the file using SQL, you can use several `pg_proaudit` functions. The `pg_proaudit_settings` view displays the current `pg_proaudit` rules, even if they have not been saved into the `pg_proaudit.conf` file yet.

All the logged events belong to the following classes:

- DDL commands for creating, changing, and deleting DBMS objects (databases, tablespaces, schemas, tables, views, sequences, languages, functions)
- access control commands for database objects (GRANT, REVOKE)
- DML commands for access to database objects (INSERT, UPDATE, DELETE, SELECT, TRUNCATE for tables and/or views, EXECUTE for functions)
- database authentication/disconnection events
- all commands executed by a particular user

Security events can be logged both in the centralized logging solution of the operating system (syslog) and in the standard file-system files. Event logs can be written both into the syslog and into the files simultaneously. For clear identification, all `pg_proaudit` records in the syslog are marked with `AUDIT`. Event log files can be written in the CEF (Common Event Format) and CSV (Comma-Separated Values) formats. Each event is logged on a separate line that contains the following fields:

- date and time of the event
- current user name
- database name
- server process ID (PID)
- severity level: `INFO` or `ERROR`
- serial number of the command in a session
- subcommand number in complex commands (CREATE TABLE ... AS SELECT ...)
- operator name
- object type
- object name
- operator execution results: `SUCCESS` or `FAILURE`
- additional information like error message in case of `FAILURE` or connection parameters for the `AUTHENTICATE` event; unfinished authentication attempts are marked as [EOF. No credentials provided]
- text of the SQL command
- parameters of the command (for example, for `PREPARE`)
- session user name
- unique ID of the event (in the [UUIDv7](#) format)
- transaction ID (XID)
- virtual transaction ID (VXID)

An event contains the information about both `session_user` and `current_user` of the session. Therefore, it will be possible to identify the user, even if they execute the `SET ROLE` command to change user identifier.

The XID and VXID values can be zero if an event does not relate to a transaction (e. g. the `DISCONNECT` event).

You can define a directory to store security log files and set up log file rotation. `pg_proaudit` can switch to a new log file either after the specified time interval, or when the specified size of the log file is exceeded. This enables you to define a workflow for cleaning up security event logs.

Postgres Pro user with the `SUPERUSER` attribute should grant access to the `pg_proaudit` extension and security event log files only to the user with the information security administrator role.

F.42.1. Installing the `pg_proaudit` Extension

The `pg_proaudit` extension is a built-in extension included into Postgres Pro Standard. To enable `pg_proaudit`, complete the following steps:

1. Add `pg_proaudit` to the `shared_preload_libraries` variable in the `postgresql.conf` file:

```
shared_preload_libraries = 'pg_proaudit'
```

2. Restart the database server for the changes to take effect. To verify that the `pg_proaudit` library was installed correctly, you can run the following command:

```
SHOW shared_preload_libraries;
```

3. In each database for which you are going to log security events, create the `pg_proaudit` extension using the following query:

```
CREATE EXTENSION pg_proaudit;
```

The `pg_proaudit` extension adds several functions for managing the `pg_proaudit.conf` file, the `pg_proaudit_settings` view that displays the current `pg_proaudit` rules and event triggers.

F.42.2. Uninstalling the `pg_proaudit` Extension

To properly uninstall `pg_proaudit`, complete the following steps:

1. Delete the `pg_proaudit` extension using the following query:

```
DROP EXTENSION pg_proaudit;
```

2. Remove `pg_proaudit` from the `shared_preload_libraries` variable in the `postgresql.conf` file.

Skip this step if you have several databases in the cluster and you want to remove the extension only for one of them. In this case, it is recommended to remove logging rules related to the corresponding database prior to uninstalling the extension.

F.42.3. Functions to Configure Security Event Logging

To configure security event logging, `pg_proaudit` provides an SQL interface that consists of several functions and the `pg_proaudit_settings` view.

```
pg_proaudit_set_rule(db_name text, event_type text, object_type text, object_name text,  
                    role_name text, comment text)
```

Creates the logging rule with the specified parameters. When the `pg_proaudit_set_rule()` function completes, security event logging starts immediately, but the `pg_proaudit.conf` file is not updated. To save the changes in the `pg_proaudit.conf` file, call the `pg_proaudit_save()` function.

Arguments:

- `db_name` — name of the database for which the logging rule is established. An empty string or NULL specified in this argument means that events are logged for all databases where the `pg_proaudit` extension is created. When set to `current_database()`, events for the current database are logged.
- `event_type` — type of the event that needs to be logged, including SQL operator names, as well as `AUTHENTICATE` and `DISCONNECT` events. When set to `ALL`, as well as when an empty string or NULL

is specified, enables logging for all events available for the specified object type. For example, for the `TABLE` object type, the `ALL` keyword enables logging for commands `SELECT`, `INSERT`, `UPDATE`, `DELETE`, `TRUNCATE`, `COPY`, as well as `CREATE`, `ALTER`, `DROP`. You can also set up logging of event classes by specifying the following values: `ALL_DDL`, `ALL_DDL_NONTEMP`, `ALL_DML`, `ALL_DML_NONTEMP`, `ALL_MOD`, `ALL_PROC`, and `ALL_ROLE`. For the full list of possible *event_type* values, see [Section F.42.5](#).

- *object_type* — type of the object for which security events need to be logged. When set to `ALL`, as well as when an empty string or the `NULL` is specified, enables logging of events for all object types. For example, specify `FOREIGN TABLE` object type for the `SELECT` event to log all attempts to access foreign tables. Use `NULL` if *event_type* is set to `AUTHENTICATE`, `DISCONNECT`, `SET`, or `RESET`, and the `ROLE` value for all events that reference user actions, such as `CREATE USER` or `DROP USER`. The following object types are supported: `COMPOSITE TYPE`, `DATABASE`, `EVENT TRIGGER`, `FUNCTION`, `INDEX`, `PREPARED STATEMENT`, `ROLE`, `SEQUENCE`, `SCHEMA`, `TABLE`, `FOREIGN TABLE`, `TOAST TABLE`, `TABLESPACE`, `VIEW`, `MATERIALIZED VIEW`, `CATALOG RELATION`, and `CATALOG FUNCTION`.

Note

To log security events for system catalog objects, it is required to enable the [pg_proaudit.log_catalog_access](#) configuration parameter. Otherwise, these events will not be logged, even if the `CATALOG RELATION`, `CATALOG FUNCTION`, or `ALL` object type is specified in the rule.

- *object_name* — name of the object for which the logging rule is established. When an empty string or `NULL` is specified, enables logging of events for all object names.
- *role_name* — name of the role for which the logging rule is established. If specified, allows logging the actions caused by the user who has the privileges of the role. This means that at least one of the user session attributes, *session_user* or *current_user*, should either be equal to the *role_name*, or be directly or indirectly a member of this role. When an empty string or `NULL` is specified, enables logging of actions caused by any user. When set to [current_role](#), the logging rule is established for the user current role.
- *comment* — comment to describe the created logging rule. This argument does not affect the rule execution and is not reflected in the log.

```
pg_proaudit_remove_rule(db_name text, event_type text, object_type text, object_name  
text, role_name text)
```

Removes the specific logging rule with the set parameters. To save the changes in the `pg_proaudit.conf` file, call the `pg_proaudit_save()` function.

Note

If the rule that you want to remove is configured to log the `DISCONNECT` event type, then disconnect events may still be logged after the rule is removed. For additional information, see [Section F.42.3.1](#).

Arguments:

- *db_name* — name of the database for which the logging rule needs to be removed.
- *event_type* — type of the event for which the logging rule needs to be removed. For the full list of possible *event_type* values, see [Section F.42.5](#).
- *object_type* — type of the object for which the logging rule needs to be removed.
- *object_name* — name of the object for which the logging rule needs to be removed.
- *role_name* — name of the role for which the logging rule needs to be removed.

```
pg_proaudit_show()
```

Returns logged events in a table view. This function is used by the `pg_proaudit_settings` view.

```
pg_proaudit_reload()
```

Reads logging configuration from the `pg_proaudit.conf` file. You must call this function if the `pg_proaudit.conf` file was modified manually using the operating system facilities.

```
pg_proaudit_reset()
```

Removes all logging rules. To save information about the canceled logging in the `pg_proaudit.conf` file, call the `pg_proaudit_save()` function.

```
pg_proaudit_save()
```

Saves logging rules from memory into the `pg_proaudit.conf` file. The `pg_proaudit.conf` file is located in the cluster data directory (PGDATA). You cannot change the `pg_proaudit.conf` file location.

F.42.3.1. Handling Database Disconnection Events

When a logging rule is configured for `DISCONNECT` event type, and a user authenticates in a database, then the `pg_proaudit` extension checks whether the corresponding disconnection event satisfies the rule and must be logged.

If the event must be logged, then the removal of the logging rule has no effect on the event. This event will be logged no matter if the logging rule exists at the moment of disconnect.

Consider the following example:

1. An administrator configures the following logging rule:

```
SELECT pg_proaudit_set_rule ('postgres', 'DISCONNECT', null, null, null, 'Any  
disconnect from the postgres DB');
```

2. A user connects to the `postgres` database and goes through authentication.

For the rule in effect, a corresponding disconnection event will be logged later.

3. The administrator removes the logging rule, while the user is still connected to the database:

```
SELECT pg_proaudit_remove_rule('postgres', 'DISCONNECT', null, null, null);
```

4. The user disconnects from the database.

The corresponding disconnection event is logged despite the removal of the logging rule.

F.42.3.2. Handling Object Names

Comparison of string representations of names for database, user, role and other objects is case-insensitive even if the object name in the database is enclosed in quotes. These string representations are stored as lower-case strings.

Strings representing object names need to be passed to functions `pg_proaudit_set_rule` and `pg_proaudit_remove_rule` as regular strings: a single quote needs repeating, and other characters are passed as is, without escaping or wrapping.

For example, rules for tables `table1` and `"TaBlE1"` will be the same, and their names can be passed in upper-case or lower-case characters. The same holds for roles. As for databases, before creating a rule, `pg_proaudit` checks whether this database actually exists, and this check is case-sensitive.

The following examples illustrate creation of "weird" object names and specifying correct audit rules for them.

```
create table "TABle'"123"();  
SELECT pg_proaudit_set_rule(current_database(), null, null, 'public.TabLe'"'"'123',  
    null, 'tst cmnt');  
create table "taBlE""123"();
```

```
SELECT pg_proaudit_set_rule(null, null, null, 'public.tablE"123', null);

create schema "(BIG!) Schema";
create table "(BIG!) Schema"."My Tab.lE"();
SELECT pg_proaudit_set_rule(null, null, null, '(BIG!) Schema.My Tab.lE', null);

create role "Some '@#$$' person" with login;
SELECT pg_proaudit_set_rule(null, 'authenticate', null, null, 'Some ''@#$$'' person');

create role "Some '@#$$' person" with superuser;
\c - "Some '@#$$' person"
SELECT pg_proaudit_set_rule(null, 'disconnect', null, null, current_user);

create database " D B 1";
SELECT pg_proaudit_set_rule(' D B 1', 'authenticate', null, null, null);

create database " D b 2";
\c " D b 2"
create extension pg_proaudit;
SELECT pg_proaudit_set_rule(current_database(), 'disconnect', null, null, null);
```

F.42.4. pg_proaudit_settings View

This view displays the current `pg_proaudit` rules, even if they have not been saved into the `pg_proaudit.conf` file yet. The `pg_proaudit_settings` view consists of the following columns:

- `db_name` (text) — name of the database for which to log security events.
- `event_type` (text) — event type to log.
- `object_type` (text) — type of the object for which security events are to be logged.
- `object_name` (text) — name of the object for which security events are to be logged.
- `role_name` (text) — the role on behalf of which logged actions are performed.
- `comment` (text) — comment to describe the created logging rule.

F.42.5. Security Events

You can configure the `pg_proaudit` extension to log classes of security events and specific events by specifying the respective value in the `event_type` argument of the `pg_proaudit_set_rule()` function.

The following classes of security events are supported:

- `ALL_DDL`: CREATE, ALTER, DROP for any database object except stored procedures and functions.
- `ALL_DDL_NONTEMP`: same as `ALL_DDL` but the scope is limited to the objects that are not contained in `pg_temp_nnn` temporary schemas.
- `ALL_DML`: SELECT, INSERT, UPDATE, DELETE, TRUNCATE for any table type; EXECUTE for functions and stored procedures.
- `ALL_DML_NONTEMP`: same as `ALL_DML` but the scope is limited to the objects that are not contained in `pg_temp_nnn` temporary schemas.
- `ALL_MOD`: INSERT, UPDATE, DELETE, TRUNCATE for any table type.
- `ALL_PROC`: CREATE, ALTER, DROP for any function and stored procedure.
- `ALL_ROLE`: CREATE, ALTER, DROP for USER, ROLE, GROUP, PROFILE, as well as execution of the GRANT command.

The following specific security events are supported:

- AUTHENTICATE
- DISCONNECT
- ALTER AGGREGATE
- ALTER COLLATION
- ALTER CONVERSION
- ALTER DATABASE
- ALTER DEFAULT PRIVILEGES
- ALTER DOMAIN

- ALTER EVENT TRIGGER
- ALTER EXTENSION
- ALTER FOREIGN DATA WRAPPER
- ALTER FOREIGN TABLE
- ALTER FUNCTION
- ALTER INDEX
- ALTER LANGUAGE
- ALTER LARGE OBJECT
- ALTER MATERIALIZED VIEW
- ALTER OPERATOR
- ALTER OPERATOR CLASS
- ALTER OPERATOR FAMILY
- ALTER POLICY
- ALTER PROFILE
- ALTER ROLE, ALTER USER, ALTER GROUP
- ALTER RULE
- ALTER SCHEMA
- ALTER SEQUENCE
- ALTER SERVER
- ALTER SYSTEM
- ALTER TABLE
- ALTER TABLESPACE
- ALTER TEXT SEARCH CONFIGURATION
- ALTER TEXT SEARCH DICTIONARY
- ALTER TEXT SEARCH PARSER
- ALTER TEXT SEARCH TEMPLATE
- ALTER TRIGGER
- ALTER TYPE
- ALTER USER MAPPING
- ALTER VIEW
- CLUSTER
- COMMENT
- COPY
- CREATE ACCESS METHOD
- CREATE AGGREGATE
- CREATE CAST
- CREATE COLLATION
- CREATE CONVERSION
- CREATE DATABASE
- CREATE DOMAIN
- CREATE EVENT TRIGGER
- CREATE EXTENSION
- CREATE FOREIGN DATA WRAPPER
- CREATE FOREIGN TABLE
- CREATE FUNCTION
- CREATE INDEX
- CREATE LANGUAGE
- CREATE MATERIALIZED VIEW
- CREATE OPERATOR
- CREATE OPERATOR CLASS
- CREATE OPERATOR FAMILY
- CREATE POLICY
- CREATE PROFILE
- CREATE ROLE, CREATE USER, CREATE GROUP
- CREATE RULE
- CREATE SCHEMA
- CREATE SEQUENCE
- CREATE SERVER

- CREATE TABLE, CREATE TABLE AS, SELECT INTO
- CREATE TABLESPACE
- CREATE TEXT SEARCH CONFIGURATION
- CREATE TEXT SEARCH DICTIONARY
- CREATE TEXT SEARCH PARSER
- CREATE TEXT SEARCH TEMPLATE
- CREATE TRANSFORM
- CREATE TRIGGER
- CREATE TYPE
- CREATE USER MAPPING
- CREATE VIEW
- DEALLOCATE
- DELETE
- DO
- DROP ACCESS METHOD
- DROP AGGREGATE
- DROP CAST
- DROP COLLATION
- DROP CONVERSION
- DROP DATABASE
- DROP DOMAIN
- DROP EVENT TRIGGER
- DROP EXTENSION
- DROP FOREIGN DATA WRAPPER
- DROP FOREIGN TABLE
- DROP FUNCTION
- DROP INDEX
- DROP LANGUAGE
- DROP MATERIALIZED VIEW
- DROP OPERATOR
- DROP OPERATOR CLASS
- DROP OPERATOR FAMILY
- DROP OWNED
- DROP POLICY
- DROP PROFILE
- DROP ROLE, DROP USER, DROP GROUP
- DROP RULE
- DROP SCHEMA
- DROP SEQUENCE
- DROP SERVER
- DROP TABLE
- DROP TABLESPACE
- DROP TEXT SEARCH CONFIGURATION
- DROP TEXT SEARCH DICTIONARY
- DROP TEXT SEARCH PARSER
- DROP TEXT SEARCH TEMPLATE
- DROP TRANSFORM
- DROP TRIGGER
- DROP TYPE
- DROP USER MAPPING
- DROP VIEW
- EXECUTE
- GRANT
- INSERT
- PREPARE
- REASSIGN OWNED
- REFRESH MATERIALIZED VIEW
- REINDEX

- RESET
- REVOKE
- SECURITY LABEL
- SELECT
- SET
- UPDATE
- TRUNCATE TABLE

F.42.6. Security Event Log Configuration Parameters

The `pg_proaudit` extension provides several configuration parameters for managing security event log files. These parameters can be set in the `postgresql.conf` configuration file, or with the help of the `ALTER SYSTEM` command. For the changes to take effect, call the `pg_reload_conf()` function or restart the database server. For additional configuration, the [syslog_ident](#) and [syslog_facility](#) configuration parameters can be used.

`pg_proaudit.log_destination (string)`

Defines the method for logging security events. Possible values are:

- `csvlog` — log security events in a CSV file.
- `ceflog` — log security events in a CEF file. CEF is an open text-based format designed for log records. It contains a standard header and a variable extension formatted as key-value pairs.
- `syslog` — log security events in syslog.

You can specify one or more values separated by commas.

Default: `csvlog`

`pg_proaudit.log_catalog_access (boolean)`

Specifies whether to log access to system catalog objects in the `pg_catalog` schema.

When set to `off`, no events will be logged, even if there are rules for the `CATALOG RELATION`, `CATALOG FUNCTION`, or `ALL` object types.

It is not recommended to set the parameter to `on`, if you do not plan to log events for system catalog objects. Doing otherwise may impact Postgres Pro performance, even if there are no rules for the aforementioned object types.

Default: `off`

`pg_proaudit.log_command_text (boolean)`

Specifies whether to log the SQL command text for security events.

Default: `on`

`pg_proaudit.log_directory (string)`

Specifies the path to the directory that stores CSV and CEF log files. This can be an absolute path or a relative path to the cluster data directory (`PGDATA`). This parameter is used if the `csvlog` or `ceflog` value is specified in the [pg_proaudit.log_destination](#) parameter.

Default: `pg_proaudit`

`pg_proaudit.log_filename (string)`

Defines the filenames of the created security event log files. The filename template can contain %-escapes, similar to the ones listed in the `strftime` specification of the Open Group (<http://pubs.opengroup.org/onlinepubs/009695399/functions/strftime.html>). This parameter is used if the `csvlog` or `ceflog` value is specified in the [pg_proaudit.log_destination](#) parameter.

Default: postgresql-%Y-%m-%d_%H%M%S.log

`pg_proaudit.log_rotation_size` (integer)

Sets the maximum size of a log file, in kilobytes. When this size is achieved, `pg_proaudit` creates a new file for logging security events. If set to 0, disables size-based creation of new log files. This parameter is used if the `csvlog` or `ceflog` value is specified in the [pg_proaudit.log_destination](#) parameter.

Default: 10MB

`pg_proaudit.log_rotation_age` (integer)

Sets the maximum lifetime of a log file, in minutes. After this timeframe is elapsed, `pg_proaudit` creates a new file for logging security events. If set to 0, disables time-based creation of new log files. This parameter is used if the `csvlog` or `ceflog` value is specified in the [pg_proaudit.log_destination](#) parameter.

Default: 1 day

`pg_proaudit.log_truncate_on_rotation` (boolean)

Specifies whether to truncate log files when logging is switched to an existing log file. If set to `off`, `pg_proaudit` appends new log entries to the end of the file. This parameter is used if the `csvlog` or `ceflog` value is specified in the [pg_proaudit.log_destination](#) parameter.

Default: `off`

`pg_proaudit.max_rules_count` (integer)

Specifies the maximum number of rules allowed. For the parameter changes to take effect, the database server must be restarted.

Default: 500

F.42.7. Viewing Security Event Log

Security event log files are text files that can be viewed by the operating system facilities. To access log files using SQL, you can use the `file_fdw` extension — a foreign data wrapper for accessing files on the database server. To use this method, complete the following steps:

1. Install the `file_fdw` and create an external server:

```
CREATE EXTENSION file_fdw;  
CREATE SERVER pg_proauditlog FOREIGN DATA WRAPPER file_fdw;
```

2. Create a foreign table, specifying the columns and the absolute path to the log file. The actual log file location is determined by the `pg_proaudit.log_directory` and `pg_proaudit.log_filename` parameters.

```
CREATE FOREIGN TABLE pg_proaudit_log  
    ( log_time timestamp(3) with time zone,  
      current_usr_name text,  
      database_name text,  
      session_pid text,  
      error_severity text,  
      session_line_num bigint,  
      session_line_subcommand_num bigint,  
      event_type text,  
      object_type text,  
      object_name text,  
      status text,
```

```
error_message text,  
query_text text,  
query_args text,  
session_usr_name text,  
uuid text,  
xid text,  
vxid text )
```

```
SERVER pg_proauditlog  
OPTIONS (filename 'absolute_file_path_to_log_file.csv', FORMAT 'csv' );
```

Make sure that the `pg_proaudit.log_destination` parameter contains the `csvlog` value, which enables writing security event logs to CSV files.

F.42.8. Examples

As an example, let's set up logging for the following security events:

- authentications/disconnections to the `postgres` database
- all actions of the user if at least one of the user session attributes, `session_user` or `current_user`, is either explicitly set to the `postgres` role, or is directly or indirectly a member of this role
- creating, updating, and deleting any tables
- all operations on the `app_table` table that belongs to the `public` schema

All events must be logged in the CSV format and stored for a week. It is required to set up SQL access to the security event log. To complete the scenario, do the following:

In `psql`, check that the preliminary setup of the `pg_proaudit` extension is complete in the `postgres` database:

```
SHOW shared_preload_libraries;  
shared_preload_libraries  
-----  
pg_proaudit  
  
\dx pg_proaudit  
List of installed extensions  
Name | Version | Schema | Description  
-----+-----+-----+-----  
pg_proaudit | 2.0 | public | provides auditing functionality
```

Add the following lines to the `postgresql.conf` configuration file:

```
pg_proaudit.log_destination = 'csvlog'  
pg_proaudit.log_directory = 'audit'  
pg_proaudit.log_filename = 'audit-%u.csv'  
pg_proaudit.log_rotation_age = 1440  
pg_proaudit.log_rotation_size = 0  
pg_proaudit.log_truncate_on_rotation = on  
pg_proaudit.log_command_text = on
```

For the changes to take effect, run the following query:

```
SELECT pg_reload_conf();
```

Check that the following parameters are set as expected:

```
SHOW pg_proaudit.log_destination;  
SHOW pg_proaudit.log_directory;  
SHOW pg_proaudit.log_filename;  
SHOW pg_proaudit.log_rotation_age;  
SHOW pg_proaudit.log_rotation_size;
```

```
SHOW pg_proaudit.log_truncate_on_rotation;  
SHOW pg_proaudit.log_command_text;
```

Suppose your PGDATA environment variable points to the cluster data directory. Since the `pg_proaudit.log_directory` defines a relative path to the log files, they will be located in the `$PGDATA/audit` directory. Let's create an empty file for each day of the week and make them available to their owner only:

```
touch $PGDATA/audit/audit-1.csv  
touch $PGDATA/audit/audit-2.csv  
touch $PGDATA/audit/audit-3.csv  
touch $PGDATA/audit/audit-4.csv  
touch $PGDATA/audit/audit-5.csv  
touch $PGDATA/audit/audit-6.csv  
touch $PGDATA/audit/audit-7.csv  
chmod 600 $PGDATA/audit/audit-*.csv
```

Create a table for reading log entries:

```
CREATE TABLE pg_proaudit_log (  
    log_time timestamp(3) with time zone,  
    current_usr_name text,  
    database_name text,  
    session_pid text,  
    error_severity text,  
    session_line_num bigint,  
    session_line_subcommand_num bigint,  
    event_type text,  
    object_type text,  
    object_name text,  
    status text,  
    error_message text,  
    query_text text,  
    query_args text,  
    session_usr_name text,  
    uuid text,  
    xid text,  
    vxid text  
);
```

Install the `file_fdw` extension and create an external server:

```
CREATE EXTENSION file_fdw;  
CREATE SERVER pg_proauditlog FOREIGN DATA WRAPPER file_fdw;
```

Now let's create seven child foreign tables for the `pg_proaudit_log` table, for each day of the week:

```
CREATE FOREIGN TABLE pg_proaudit_log_1 () INHERITS (pg_proaudit_log) SERVER  
pg_proauditlog  
    OPTIONS (filename '/path_to_PGDATA/audit/audit-1.csv', FORMAT 'csv');  
CREATE FOREIGN TABLE pg_proaudit_log_2 () INHERITS (pg_proaudit_log) SERVER  
pg_proauditlog  
    OPTIONS (filename '/path_to_PGDATA/audit/audit-2.csv', FORMAT 'csv');  
CREATE FOREIGN TABLE pg_proaudit_log_3 () INHERITS (pg_proaudit_log) SERVER  
pg_proauditlog  
    OPTIONS (filename '/path_to_PGDATA/audit/audit-3.csv', FORMAT 'csv');  
CREATE FOREIGN TABLE pg_proaudit_log_4 () INHERITS (pg_proaudit_log) SERVER  
pg_proauditlog  
    OPTIONS (filename '/path_to_PGDATA/audit/audit-4.csv', FORMAT 'csv');  
CREATE FOREIGN TABLE pg_proaudit_log_5 () INHERITS (pg_proaudit_log) SERVER  
pg_proauditlog  
    OPTIONS (filename '/path_to_PGDATA/audit/audit-5.csv', FORMAT 'csv');
```

**Additional Supplied Modules
and Extensions Shipped in
postgrespro-std-16-contrib**

```
CREATE FOREIGN TABLE pg_proaudit_log_6 () INHERITS (pg_proaudit_log) SERVER
pg_proauditlog
  OPTIONS (filename '/path_to_PGDATA/audit/audit-6.csv', FORMAT 'csv');
CREATE FOREIGN TABLE pg_proaudit_log_7 () INHERITS (pg_proaudit_log) SERVER
pg_proauditlog
  OPTIONS (filename '/path_to_PGDATA/audit/audit-7.csv', FORMAT 'csv');
```

To set up logging for the required security events, connect to the postgres database and execute the following commands:

```
SELECT pg_proaudit_set_rule (current_database(), 'AUTHENTICATE', null, null, null, 'Any
authentication in the current DB');
SELECT pg_proaudit_set_rule (current_database(), 'DISCONNECT', null, null, null, 'Any
disconnect from the current DB');
SELECT pg_proaudit_set_rule (current_database(), 'ALL', 'TABLE', null, null, 'Any
operations with any table in the current DB');
SELECT pg_proaudit_set_rule (current_database(), 'ALL', null, null, 'postgres', 'Any
operation by "postgres" user in the current DB');
```

Create the app_table table and enable logging for all operations on this table:

```
CREATE TABLE app_table (id int, name text);
SELECT pg_proaudit_set_rule (current_database(), 'ALL', null, 'public.app_table',
null);
```

Check that event logging is configured as expected:

```
SELECT * FROM pg_proaudit_settings;
db_name | event_type | object_type | object_name | role_name |
comment
-----+-----+-----+-----+-----+-----
+-----+-----+-----+-----+-----+-----
postgres | authenticate | ALL | | | Any
authentication in the current DB
postgres | disconnect | ALL | | | Any disconnect
from the current DB
postgres | ALL | table | | | Any operations
with any table in the current DB
postgres | ALL | ALL | | postgres | Any operation
by "postgres" user in the current DB
postgres | ALL | ALL | public.app_table | |
(5 rows)
```

Save these logging rules into the pg_proaudit.conf file, so that they are not lost after the server restart:

```
SELECT pg_proaudit_save();
```

Let's run several queries on the app_table table:

```
INSERT INTO app_table VALUES (1, 'first');
SELECT * FROM app_table;
```

Check the log entries for the app_table table:

```
SELECT to_char(log_time, 'DD.MM.YY HH24:MI:SS') AS when, current_usr_name,
session_pid, event_type, query_text, session_usr_name
FROM pg_proaudit_log
WHERE object_name = 'public.app_table';
when | current_usr_name | session_pid | event_type |
query_text | session_usr_name
-----+-----+-----+-----+-----+-----
+-----+-----+-----+-----+-----+-----
```

Additional Supplied Modules

app_table;				
postgres				
(3 rows)				

We have set up a weekly rotation of log files, with the log file switched once a day. It means that queries to the `pg_proaudit_log` table will return only those security events that have happened in the latest week. Older events will be automatically removed at log file rotation. To define additional access constraints for specific log entries, you can create separate views based on queries to the `pg_proaudit_log` table and grant read rights to such views using built-in Postgres Pro access control methods.

F.43. pgpro_bindump — a replication protocol module for backup and restore

pgpro_bindump is a module designed to implement additional commands for the Postgres Pro replication protocol, specifically for use with the [pg_probackup3](#) utility. pgpro_bindump offers the following benefits:

- **Simplified communication:** pgpro_bindump does not require the SSH protocol and associated configurations to connect to a database server.
- **Integrated WAL transfer:** WAL files are transferred together with data files, reducing the risk of data loss during backups.
- **Optimized storage:** Files are not copied as they are, but are archived using the pg_probackup3 own format, CBOR (RFC 8949 Concise Binary Object Representation), which enhances the storage efficiency.

F.43.1. Architecture

A dedicated backend process is created to handle connections from external applications. You can use the pg_probackup3 utility or a custom application to send requests to this backend.

Multiple connections can be established for the same application if needed.

Since the pgpro_bindump module has direct access to the database files, it does not require any additional permissions.

pgpro_bindump uses the [libpgprobackup](#), along with its built-in encoder module, to send data to the application.

The walsender_plugin_libraries plugin has been added to simplify the process of adding and utilizing new replication commands, including custom ones.

F.43.2. Limitations and Requirements

pgpro_bindump currently has the following limitations and requirements:

- `libpgprobackup.so` and `libpb3_encoder.so` are required for pgpro_bindump operation.

F.43.3. Installation and Setup

The pgpro_bindump module is included in Postgres Pro as part of the postgrespro-std-16-contrib package (for the installation instructions, see [Chapter 16](#)). Once you complete Postgres Pro installation, follow the steps below.

1. Specify the following parameters in the `postgresql.conf` file:

```
shared_preload_libraries = 'pgpro_bindump'
wal_level = 'replica' # or 'logical'
walsender_plugin_libraries = 'pgpro_bindump'
```

2. Restart the Postgres Pro instance.

F.43.4. Replication Commands

The pgpro_bindump module implements the following replication commands:

- `just-noop` — a do-nothing command.
- `start_backup` — starts the backup process.
- `copy_files` — copies files in the CBOR format.

- `stop_backup` — stops the backup process.

The backup process runs in the PRO mode — an advanced data source mode that incorporates all available optimizations and enhancements, including the proprietary replication protocol and specialized replication commands.

To send commands from a user application to `pgpro_bindump` and to receive the output data from `pgpro_bindump` by the application, use `libpq`.

Note

An established connection to a running Postgres Pro server is required.

F.43.4.1. `start_backup`

```
start_backup LABEL label, INCR_MODE incr_mode, START_LSN start_lsn,  
TRANSFER_MODE transfer_mode,  
[TRANSFER_BUFFER_SIZE buffer_size]
```

Starts the backup process. Sends the following data to the application:

- `start_lsn` — LSN at the start of the backup.
- `start_tli` — the timeline ID at the start of the backup.
- `min_xid` — the minimal transaction ID at the start of the backup.
- `min_multixact` — the minimal multixact ID at the start of the backup.
- `tablespace_list` — a list of tablespaces included in the backup.
- `database_list` — a list of databases included in the backup.

`LABEL label`

The name of the backup.

`INCR_MODE incr_mode`

The type of incremental backup. Possible values: `PTRACK`, `DELTA`.

`START_LSN start_lsn`

An `XLogRecPtr` value representing LSN at the start of the backup.

`TRANSFER_MODE transfer_mode`

The method to be used for sending data from a server to an application. Possible values:

- `raw` — unpacked data is sent in random blocks of arbitrary size.
- `packed` — packed data is sent in blocks of 128 KB with a common header.

`packed` is the default value.

`TRANSFER_BUFFER_SIZE buffer_size`

A numeric value representing the buffer size. The preset (unchanged) value is 131072 (128 KB).

F.43.4.2. `copy_files`

```
copy_files VERIFY_CHECKSUMS [TRUE | FALSE], COMPRESS_ALG compress_alg,  
COMPRESS_LVL compress_lvl, TRANSFER_MODE transfer_mode,  
[INCR_MODE incr_mode], [START_LSN start_lsn], [TRANSFER_BUFFER_SIZE buffer_size],  
[WORKER_INFO number_of_workers:worker_id]
```

Forwards blocks of data files and WAL files packaged in the CBOR format.

VERIFY_CHECKSUMS

A boolean value (`true` or `false`) indicating whether to verify checksums.

COMPRESS_ALG *compress_alg*

The compression algorithm to be used. Possible values: `zlib`, `zstd`, `lz4`, `none`.

COMPRESS_LVL *compress_lvl*

The compression level. Possible values: 1, 2, 3, 4, 5.

TRANSFER_MODE *transfer_mode*

The method to be used for sending data from a server to an application. Possible values:

- `raw` — unpacked data is sent in random blocks of arbitrary size.
- `packed` — packed data is sent in blocks of 128 KB with a common header.

`packed` is the default value.

INCR_MODE *incr_mode*

The type of incremental backup. Possible values: `PTRACK`, `DELTA`.

START_LSN *start_lsn*

An `XLogRecPtr` value representing LSN at the start of the backup.

TRANSFER_BUFFER_SIZE *buffer_size*

A numeric value representing the buffer size. The preset (unchanged) value is 131072 (128 KB).

WORKER_INFO *number_of_workers:worker_id*

The number of workers and the worker ID.

F.43.4.3. stop_backup

```
stop_backup STREAM [TRUE | FALSE], COMPRESS_ALG compress_alg,  
COMPRESS_LVL compress_lvl,  
[EXTERNALS externals] [TRANSFER_BUFFER_SIZE buffer_size], [TRANSFER_MODE transfer_mode]
```

Completes the copy process and closes the existing connection. Sends the following data to the application:

- `stop_lsn` — LSN at the end of the backup.
- `stop_tli` — the timeline ID at the end of the backup.
- The `backup.control` file.
- A set of WAL files (only if WAL streaming is enabled).

STREAM

A boolean value (`true` or `false`) indicating whether WAL streaming is enabled.

COMPRESS_ALG *compress_alg*

The compression algorithm to be used. Possible values: `zlib`, `zstd`, `lz4`, `none`.

COMPRESS_LVL *compress_lvl*

The compression level. Possible values: 1, 2, 3, 4, 5.

EXTERNALS *externals*

A list of external directories.

TRANSFER_BUFFER_SIZE *buffer_size*

A numeric value representing the buffer size. The preset (unchanged) value is 131072 (128 KB).

TRANSFER_MODE *transfer_mode*

The method to be used for sending data from a server to an application. Possible values:

- `raw` — unpacked data is sent in random blocks of arbitrary size.
- `packed` — packed data is sent in blocks of 128 KB with a common header.

`packed` is the default value.

F.43.5. Authors

Postgres Professional, Moscow, Russia.

F.44. pg_prewarm — preload relation data into buffer caches

The `pg_prewarm` module provides a convenient way to load relation data into either the operating system buffer cache or the Postgres Pro buffer cache. Prewarming can be performed manually using the `pg_prewarm` function, or can be performed automatically by including `pg_prewarm` in [shared_preload_libraries](#). In the latter case, the system will run a background worker which periodically records the contents of shared buffers in a file called `autoprewarm.blocks` and will, using 2 background workers, reload those same blocks after a restart.

F.44.1. Functions

```
pg_prewarm(regclass, mode text default 'buffer', fork text default 'main',  
           first_block int8 default null,  
           last_block int8 default null) RETURNS int8
```

The first argument is the relation to be prewarmed. The second argument is the prewarming method to be used, as further discussed below; the third is the relation fork to be prewarmed, usually `main`. The fourth argument is the first block number to prewarm (`NULL` is accepted as a synonym for zero). The fifth argument is the last block number to prewarm (`NULL` means prewarm through the last block in the relation). The return value is the number of blocks prewarmed.

There are three available prewarming methods. `prefetch` issues asynchronous prefetch requests to the operating system, if this is supported, or throws an error otherwise. `read` reads the requested range of blocks; unlike `prefetch`, this is synchronous and supported on all platforms and builds, but may be slower. `buffer` reads the requested range of blocks into the database buffer cache.

Note that with any of these methods, attempting to prewarm more blocks than can be cached — by the OS when using `prefetch` or `read`, or by Postgres Pro when using `buffer` — will likely result in lower-numbered blocks being evicted as higher numbered blocks are read in. Prewarmed data also enjoys no special protection from cache evictions, so it is possible that other system activity may evict the newly prewarmed blocks shortly after they are read; conversely, prewarming may also evict other data from cache. For these reasons, prewarming is typically most useful at startup, when caches are largely empty.

```
autoprewarm_start_worker() RETURNS void
```

Launch the main autoprewarm worker. This will normally happen automatically, but is useful if automatic prewarm was not configured at server startup time and you wish to start up the worker at a later time.

```
autoprewarm_dump_now() RETURNS int8
```

Update `autoprewarm.blocks` immediately. This may be useful if the autoprewarm worker is not running but you anticipate running it after the next restart. The return value is the number of records written to `autoprewarm.blocks`.

F.44.2. Configuration Parameters

```
pg_prewarm.autoprewarm (boolean)
```

Controls whether the server should run the autoprewarm worker. This is on by default. This parameter can only be set at server start.

```
pg_prewarm.autoprewarm_interval (integer)
```

This is the interval between updates to `autoprewarm.blocks`. The default is 300 seconds. If set to 0, the file will not be dumped at regular intervals, but only when the server is shut down.

These parameters must be set in `postgresql.conf`. Typical usage might be:

```
# postgresql.conf
```

```
shared_preload_libraries = 'pg_prewarm'
```

```
pg_prewarm.autoprewarm = true  
pg_prewarm.autoprewarm_interval = 300s
```

Robert Haas <rhaas@postgresql.org>

F.45. pg_query_state — a facility to know the current state of query execution on working backend

The `pg_query_state` module provides facility to know the current state of query execution on working backend.

F.45.1. Overview

Each non-utility query statement (SELECT/INSERT/UPDATE/DELETE) after optimization/planning stage is translated into plan tree, which is kind of imperative representation of declarative SQL query. EXPLAIN ANALYZE request allows to demonstrate execution statistics gathered from each node of plan tree (full time of execution, number of rows emitted to upper nodes, etc). But this statistics is collected after execution of query. This module allows to show actual statistics of query running on external backend. At that, format of resulting output is almost identical to ordinal EXPLAIN ANALYZE. Thus users are able to track of query execution in progress. In fact, this module is able to explore external backend and determine its actual state. Particularly it's helpful when backend executes a heavy query or gets stuck.

F.45.2. Use cases

Using this module there can help in the following things:

- detect a long query (along with other monitoring tools);
- supervise query execution.

F.45.3. Installation

To install `pg_query_state`, complete the following steps:

1. Add the library name to the `shared_preload_libraries` parameter in the `postgresql.conf` file as follows:

```
shared_preload_libraries = 'pg_query_state'
```

2. Reload the database server for the changes to take effect.
3. Create the `pg_query_state` extension using the following query:

```
CREATE EXTENSION pg_query_state;
```

4. If you need to upgrade the `pg_query_state` extension, use `ALTER EXTENSION UPDATE`.

F.45.4. Functions

F.45.4.1. pg_query_state

```
pg_query_state (integer pid,  
                verbose boolean DEFAULT FALSE,  
                costs    boolean DEFAULT FALSE,  
                timing    boolean DEFAULT FALSE,  
                buffers   boolean DEFAULT FALSE,  
                triggers  boolean DEFAULT FALSE,  
                format    text    DEFAULT 'text')  
  
returns TABLE (pid integer,  
                frame_number integer,  
                query_text text,  
                plan text,  
                leader_pid integer)
```

Extract current query state from backend with specified `pid`. Since parallel query can spawn multiple workers and function call causes nested subqueries so that state of execution may be viewed as stack of running queries, return value of `pg_query_state` has type `TABLE (pid integer, frame_number integer, query_text text, plan text, leader_pid integer)`. It represents tree structure consisting of leader

process and its spawned workers identified by `pid`. Each worker refers to leader through `leader_pid` column. For leader process the value of this column is `null`. The state of each process is represented as stack of function calls. Each frame of that stack is specified as correspondence between `frame_number` starting from zero, `query_text` and `plan` with online statistics columns.

Thus, user can see the states of main query and queries generated from function calls for leader process and all workers spawned from it.

In process of execution some nodes of plan tree can take loops of full execution. Therefore statistics for each node consists of two parts: average statistics for previous loops just like in `EXPLAIN ANALYZE` output and statistics for current loop if node have not finished.

Optional arguments:

- `verbose` - use `EXPLAIN VERBOSE` for plan printing;
- `costs` - costs for each node;
- `timing` - print timing data for each node, if collecting of timing statistics is turned off on called side resulting output will contain WARNING message `timing statistics disabled`;
- `buffers` - print buffers usage, if collecting of buffers statistics is turned off on called side resulting output will contain WARNING message `buffers statistics disabled`;
- `triggers` - include triggers statistics in result plan trees;
- `format` - `EXPLAIN` format to be used for plans printing, possible values: `text`, `xml`, `json`, `yaml`.

If callable backend is not executing any query the function prints INFO message about backend's state taken from `pg_stat_activity` view if it exists there.

Calling role have to be superuser or member of the role whose backend is being called. Otherwise function prints ERROR message `permission denied`.

F.45.4.2. `pg_progress_bar`

```
pg_progress_bar (integer pid)
    returns FLOAT
```

Returns the current progress of query execution. This function extracts the state of the current query from the backend process with the specified `pid`. Then, it collects the actual and expected row counts from all plan nodes, and computes the overall progress ratio for the entire execution tree. As a result, the function returns a numeric value from 0 to 1 that means the query execution progress.

This function can be used in the Postgres Pro GUI to display the graphical progress bar indicator.

If there is no information about the current query state or it is impossible to calculate the query execution progress, the corresponding message is displayed.

This function can be called only by members of the role that owns the backend process or superusers.

F.45.4.3. `pg_progress_bar_visual`

```
pg_progress_bar_visual (integer pid,
                        integer delay)
    returns VOID
```

Cyclically calculates the current progress of query execution and prints it in the text form. The function extracts the state of the current query from the backend process with the specified `pid` with the interval defined in the `delay` parameter (in seconds).

This function is a cyclic version of the [pg_progress_bar](#) function but returns `void`. Unlike `pg_progress_bar`, the `pg_progress_bar_visual` function can be used to track the query execution progress without using the GUI.

If there is no information about the current query state or it is impossible to calculate the query execution progress, the corresponding message is displayed.

This function can be called only by members of the role that owns the backend process or superusers.

F.45.5. Configuration settings

There are several user-accessible GUC variables designed to toggle the whole module and the collecting of specific statistic parameters while query is running:

- `pg_query_state.enable` - disable (or enable) `pg_query_state` completely, default value is `true`
- `pg_query_state.enable_timing` - collect timing data for each node, default value is `false`
- `pg_query_state.enable_buffers` - collect buffers usage, default value is `false`

These parameters are set on called side before running any queries whose states are attempted to extract. **WARNING:** if `pg_query_state.enable_timing` is turned off the calling side cannot get time statistics, similarly for `pg_query_state.enable_buffers` parameter.

F.45.6. Usage Examples

Set maximum number of parallel workers on `gather` node equals 2:

```
postgres=# set max_parallel_workers_per_gather = 2;
```

Assume one backend with `pid = 49265` performs a simple query:

```
postgres=# select pg_backend_pid();
pg_backend_pid
-----
    49265
(1 row)
postgres=# select count(*) from foo join bar on foo.c1=bar.c1;
```

Other backend can extract intermediate state of execution that query:

```
postgres=# \x
postgres=# select * from pg_query_state(49265);
-[ RECORD
  1 ]+-----
pid          | 49265
frame_number | 0
query_text   | select count(*) from foo join bar on foo.c1=bar.c1;
plan         | Finalize Aggregate (Current loop: actual rows=0, loop number=1)
              |
              |      -> Gather (Current loop: actual rows=0, loop number=1)
              |
              |      Workers Planned: 2
              |
              |      Workers Launched: 2
              |
              |      -> Partial Aggregate (Current loop: actual rows=0, loop
number=1)
              |
              |      -> Nested Loop (Current loop: actual rows=12, loop
number=1)
              |
              |      Join Filter: (foo.c1 = bar.c1)
              |
              |      Rows Removed by Join Filter: 5673232

leader_pid   | 49265

```

In example above working backend spawns two parallel workers with pids 49324 and 49323. Their leader_pid column's values clarify that these workers belong to the main backend. Seq Scan node has statistics on passed loops (average number of rows delivered to Nested Loop and number of passed loops are shown) and statistics on current loop. Other nodes has statistics only for current loop as this loop is first (loop number = 1).

Assume first backend executes some function:

```
postgres=# select n_join_foo_bar();
```

Other backend can get the follow output:

```

postgres=# select * from pg_query_state(49265);
-[ RECORD
1 ]+-----
pid          | 49265
frame_number | 0
query_text   | select n_join_foo_bar();
plan         | Result (Current loop: actual rows=0, loop number=1)
leader_pid   | (null)
-[ RECORD
2 ]+-----
pid          | 49265

```

**Additional Supplied Modules

```

frame_number | 1
query_text   | SELECT (select count(*) from foo join bar on foo.c1=bar.c1)
plan         | Result (Current loop: actual rows=0, loop number=1)
              +
              |   InitPlan 1 (returns $0)
              +
              |   -> Aggregate (Current loop: actual rows=0, loop number=1)
              +
              |   -> Nested Loop (Current loop: actual rows=51, loop number=1)
              +
              |           Join Filter: (foo.c1 = bar.c1)
              +
              |           Rows Removed by Join Filter: 51636304
              +
              |   -> Seq Scan on bar (Current loop: actual rows=52, loop
number=1)      +
              |   -> Materialize (actual rows=1000000 loops=51) (Current
loop: actual rows=636355, loop number=52)+
              |   -> Seq Scan on foo (Current loop: actual
rows=1000000, loop number=1)
leader_pid   | (null)

```

First row corresponds to function call, second - to query which is in the body of that function.

We can get result plans in different format (e.g. json):

```

postgres=# select * from pg_query_state(pid := 49265, format := 'json');
-[ RECORD 1 ]+-----
pid          | 49265
frame_number | 0

F.45.7. Progress Bar Usage Examples

The first backend process executes the following sample query:

```
postgres=# insert into table_name select generate_series(1,10000000);
```

Another backend process can get the execution process of the query above as follows:

```
postgres=# SELECT pid FROM pg_stat_activity where query like 'insert%';
 pid
-----
 23877
(1 row)
```

```
postgres=# SELECT pg_progress_bar(23877);
 pg_progress_bar
-----
          0.6087927
(1 row)
```

To display a visual representation of the query execution progress, run the following query:

```
postgres=# SELECT pg_progress_bar_visual(23877, 1);
Progress = 0.043510
Progress = 0.085242
Progress = 0.124921
Progress = 0.168168
Progress = 0.213803
Progress = 0.250362
Progress = 0.292632
Progress = 0.331454
Progress = 0.367509
Progress = 0.407450
Progress = 0.448646

F.46. pgrowlocks — show a table's row locking information

The `pgrowlocks` module provides a function to show row locking information for a specified table.

By default use is restricted to superusers, roles with privileges of the `pg_stat_scan_tables` role, and users with `SELECT` permissions on the table.

F.46.1. Overview

`pgrowlocks(text)` returns `setof record`

The parameter is the name of a table. The result is a set of records, with one row for each locked row within the table. The output columns are shown in [Table F.26](#).

Table F.26. `pgrowlocks` Output Columns

Name	Type	Description
<code>locked_row</code>	<code>tid</code>	Tuple ID (TID) of locked row
<code>locker</code>	<code>xid</code>	Transaction ID of locker, or multixact ID if multitransaction; see Section 71.1
<code>multi</code>	<code>boolean</code>	True if locker is a multitransaction
<code>xids</code>	<code>xid[]</code>	Transaction IDs of lockers (more than one if multitransaction)
<code>modes</code>	<code>text[]</code>	Lock mode of lockers (more than one if multitransaction), an array of Key Share, Share, For No Key Update, No Key Update, For Update, Update.
<code>pids</code>	<code>integer[]</code>	Process IDs of locking backends (more than one if multitransaction)

`pgrowlocks` takes `AccessShareLock` for the target table and reads each row one by one to collect the row locking information. This is not very speedy for a large table. Note that:

1. If an `ACCESS EXCLUSIVE` lock is taken on the table, `pgrowlocks` will be blocked.
2. `pgrowlocks` is not guaranteed to produce a self-consistent snapshot. It is possible that a new row lock is taken, or an old lock is freed, during its execution.

`pgrowlocks` does not show the contents of locked rows. If you want to take a look at the row contents at the same time, you could do something like this:

```
SELECT * FROM accounts AS a, pgrowlocks('accounts') AS p
WHERE p.locked_row = a.ctid;
```

Be aware however that such a query will be very inefficient.

F.46.2. Sample Output

```
=# SELECT * FROM pgrowlocks('t1');
locked_row | locker | multi | xids  | modes          | pids
-----+-----+-----+-----+-----+-----
(0,1)      |      609 | f      | {609} | {"For Share"}  | {3161}
(0,2)      |      609 | f      | {609} | {"For Share"}  | {3161}
(0,3)      |      607 | f      | {607} | {"For Update"} | {3107}
```

F.47. pg_stat_statements — track statistics of SQL planning and execution

The `pg_stat_statements` module provides a means for tracking planning and execution statistics of all SQL statements executed by a server.

The module must be loaded by adding `pg_stat_statements` to [shared_preload_libraries](#) in `postgresql.conf`, because it requires additional shared memory. This means that a server restart is needed to add or remove the module. In addition, query identifier calculation must be enabled in order for the module to be active, which is done automatically if `compute_query_id` is set to `auto` or `on`, or any third-party module that calculates query identifiers is loaded.

When `pg_stat_statements` is active, it tracks statistics across all databases of the server. To access and manipulate these statistics, the module provides views `pg_stat_statements` and `pg_stat_statements_info`, and the utility functions `pg_stat_statements_reset` and `pg_stat_statements`. These are not available globally but can be enabled for a specific database with `CREATE EXTENSION pg_stat_statements`.

F.47.1. The pg_stat_statements View

The statistics gathered by the module are made available via a view named `pg_stat_statements`. This view contains one row for each distinct combination of database ID, user ID, query ID and whether it's a top-level statement or not (up to the maximum number of distinct statements that the module can track). The columns of the view are shown in [Table F.27](#).

Table F.27. pg_stat_statements Columns

Column Type	Description
<code>userid oid</code> (references <code>pg_authid .oid</code>)	OID of user who executed the statement
<code>dbid oid</code> (references <code>pg_database .oid</code>)	OID of database in which the statement was executed
<code>toplevel bool</code>	True if the query was executed as a top-level statement (always true if <code>pg_stat_statements.track</code> is set to <code>top</code>)
<code>queryid bigint</code>	Hash code to identify identical normalized queries.
<code>query text</code>	Text of a representative statement
<code>plans bigint</code>	Number of times the statement was planned (if <code>pg_stat_statements.track_planning</code> is enabled, otherwise zero)
<code>total_plan_time double precision</code>	Total time spent planning the statement, in milliseconds (if <code>pg_stat_statements.track_planning</code> is enabled, otherwise zero)
<code>min_plan_time double precision</code>	Minimum time spent planning the statement, in milliseconds (if <code>pg_stat_statements.track_planning</code> is enabled, otherwise zero)
<code>max_plan_time double precision</code>	Maximum time spent planning the statement, in milliseconds (if <code>pg_stat_statements.track_planning</code> is enabled, otherwise zero)
<code>mean_plan_time double precision</code>	

Additional Supplied Modules
and Extensions Shipped in
postgrespro-std-16-contrib

Column Type	Description
	Mean time spent planning the statement, in milliseconds (if <code>pg_stat_statements.track_planning</code> is enabled, otherwise zero)
<code>stddev_plan_time</code> double precision	Population standard deviation of time spent planning the statement, in milliseconds (if <code>pg_stat_statements.track_planning</code> is enabled, otherwise zero)
<code>calls</code> bigint	Number of times the statement was executed
<code>total_exec_time</code> double precision	Total time spent executing the statement, in milliseconds
<code>min_exec_time</code> double precision	Minimum time spent executing the statement, in milliseconds
<code>max_exec_time</code> double precision	Maximum time spent executing the statement, in milliseconds
<code>mean_exec_time</code> double precision	Mean time spent executing the statement, in milliseconds
<code>stddev_exec_time</code> double precision	Population standard deviation of time spent executing the statement, in milliseconds
<code>rows</code> bigint	Total number of rows retrieved or affected by the statement
<code>shared_blks_hit</code> bigint	Total number of shared block cache hits by the statement
<code>shared_blks_read</code> bigint	Total number of shared blocks read by the statement
<code>shared_blks_dirtied</code> bigint	Total number of shared blocks dirtied by the statement
<code>shared_blks_written</code> bigint	Total number of shared blocks written by the statement
<code>local_blks_hit</code> bigint	Total number of local block cache hits by the statement
<code>local_blks_read</code> bigint	Total number of local blocks read by the statement
<code>local_blks_dirtied</code> bigint	Total number of local blocks dirtied by the statement
<code>local_blks_written</code> bigint	Total number of local blocks written by the statement
<code>temp_blks_read</code> bigint	Total number of temp blocks read by the statement
<code>temp_blks_written</code> bigint	Total number of temp blocks written by the statement
<code>blk_read_time</code> double precision	Total time the statement spent reading data file blocks, in milliseconds (if track_io_timing is enabled, otherwise zero)
<code>blk_write_time</code> double precision	Total time the statement spent writing data file blocks, in milliseconds (if track_io_timing is enabled, otherwise zero)
<code>temp_blk_read_time</code> double precision	

Column Type	Description
	Total time the statement spent reading temporary file blocks, in milliseconds (if track_io_timing is enabled, otherwise zero)
temp_blk_write_time double precision	Total time the statement spent writing temporary file blocks, in milliseconds (if track_io_timing is enabled, otherwise zero)
wal_records bigint	Total number of WAL records generated by the statement
wal_fpi bigint	Total number of WAL full page images generated by the statement
wal_bytes numeric	Total amount of WAL generated by the statement in bytes
jit_functions bigint	Total number of functions JIT-compiled by the statement
jit_generation_time double precision	Total time spent by the statement on generating JIT code, in milliseconds
jit_inlining_count bigint	Number of times functions have been inlined
jit_inlining_time double precision	Total time spent by the statement on inlining functions, in milliseconds
jit_optimization_count bigint	Number of times the statement has been optimized
jit_optimization_time double precision	Total time spent by the statement on optimizing, in milliseconds
jit_emission_count bigint	Number of times code has been emitted
jit_emission_time double precision	Total time spent by the statement on emitting code, in milliseconds

For security reasons, only superusers and roles with privileges of the `pg_read_all_stats` role are allowed to see the SQL text and `queryid` of queries executed by other users. Other users can see the statistics, however, if the view has been installed in their database.

Plannable queries (that is, `SELECT`, `INSERT`, `UPDATE`, `DELETE`, and `MERGE`) and utility commands are combined into a single `pg_stat_statements` entry whenever they have identical query structures according to an internal hash calculation. Typically, two queries will be considered the same for this purpose if they are semantically equivalent except for the values of literal constants appearing in the query.

Note

The following details about constant replacement and `queryid` only apply when [compute_query_id](#) is enabled. If you use an external module instead to compute `queryid`, you should refer to its documentation for details.

When a constant's value has been ignored for purposes of matching the query to other queries, the constant is replaced by a parameter symbol, such as `$1`, in the `pg_stat_statements` display. The rest of the query text is that of the first query that had the particular `queryid` hash value associated with the `pg_stat_statements` entry.

Queries on which normalization can be applied may be observed with constant values in `pg_stat_statements`, especially when there is a high rate of entry deallocations. To reduce the likelihood of this hap-

pening, consider increasing `pg_stat_statements.max`. The `pg_stat_statements_info` view, discussed below in [Section F.47.2](#), provides statistics about entry deallocations.

In some cases, queries with visibly different texts might get merged into a single `pg_stat_statements` entry. Normally this will happen only for semantically equivalent queries, but there is a small chance of hash collisions causing unrelated queries to be merged into one entry. (This cannot happen for queries belonging to different users or databases, however.)

Since the `queryid` hash value is computed on the post-parse-analysis representation of the queries, the opposite is also possible: queries with identical texts might appear as separate entries, if they have different meanings as a result of factors such as different `search_path` settings.

Consumers of `pg_stat_statements` may wish to use `queryid` (perhaps in combination with `dbid` and `userid`) as a more stable and reliable identifier for each entry than its query text. However, it is important to understand that there are only limited guarantees around the stability of the `queryid` hash value. Since the identifier is derived from the post-parse-analysis tree, its value is a function of, among other things, the internal object identifiers appearing in this representation. This has some counterintuitive implications. For example, `pg_stat_statements` will consider two apparently-identical queries to be distinct, if they reference a table that was dropped and recreated between the executions of the two queries. The hashing process is also sensitive to differences in machine architecture and other facets of the platform. Furthermore, it is not safe to assume that `queryid` will be stable across major versions of Postgres Pro.

Two servers participating in replication based on physical WAL replay can be expected to have identical `queryid` values for the same query. However, logical replication schemes do not promise to keep replicas identical in all relevant details, so `queryid` will not be a useful identifier for accumulating costs across a set of logical replicas. If in doubt, direct testing is recommended.

Generally, it can be assumed that `queryid` values are stable between minor version releases of PostgreSQL, providing that instances are running on the same machine architecture and the catalog meta-data details match. Compatibility will only be broken between minor versions as a last resort.

The parameter symbols used to replace constants in representative query texts start from the next number after the highest `$n` parameter in the original query text, or `$1` if there was none. It's worth noting that in some cases there may be hidden parameter symbols that affect this numbering. For example, PL/pgSQL uses hidden parameter symbols to insert values of function local variables into queries, so that a PL/pgSQL statement like `SELECT i + 1 INTO j` would have representative text like `SELECT i + $2`.

The representative query texts are kept in an external disk file, and do not consume shared memory. Therefore, even very lengthy query texts can be stored successfully. However, if many long query texts are accumulated, the external file might grow unmanageably large. As a recovery method if that happens, `pg_stat_statements` may choose to discard the query texts, whereupon all existing entries in the `pg_stat_statements` view will show null `query` fields, though the statistics associated with each `queryid` are preserved. If this happens, consider reducing `pg_stat_statements.max` to prevent recurrences.

`plans` and `calls` aren't always expected to match because planning and execution statistics are updated at their respective end phase, and only for successful operations. For example, if a statement is successfully planned but fails during the execution phase, only its planning statistics will be updated. If planning is skipped because a cached plan is used, only its execution statistics will be updated.

F.47.2. The `pg_stat_statements_info` View

The statistics of the `pg_stat_statements` module itself are tracked and made available via a view named `pg_stat_statements_info`. This view contains only a single row. The columns of the view are shown in [Table F.28](#).

Table F.28. `pg_stat_statements_info` Columns

Column Type	Description
	dealloc bigint

Column Type	Description
	Total number of times <code>pg_stat_statements</code> entries about the least-executed statements were deallocated because more distinct statements than <code>pg_stat_statements.max</code> were observed
<code>stats_reset</code> timestamp with time zone	Time at which all statistics in the <code>pg_stat_statements</code> view were last reset.

F.47.3. Functions

`pg_stat_statements_reset(userid Oid, dbid Oid, queryid bigint)` returns void

`pg_stat_statements_reset` discards statistics gathered so far by `pg_stat_statements` corresponding to the specified `userid`, `dbid` and `queryid`. If any of the parameters are not specified, the default value 0 (invalid) is used for each of them and the statistics that match with other parameters will be reset. If no parameter is specified or all the specified parameters are 0 (invalid), it will discard all statistics. If all statistics in the `pg_stat_statements` view are discarded, it will also reset the statistics in the `pg_stat_statements_info` view. By default, this function can only be executed by superusers. Access may be granted to others using `GRANT`.

`pg_stat_statements(showtext boolean)` returns setof record

The `pg_stat_statements` view is defined in terms of a function also named `pg_stat_statements`. It is possible for clients to call the `pg_stat_statements` function directly, and by specifying `showtext := false` have query text be omitted (that is, the `OUT` argument that corresponds to the view's `query` column will return nulls). This feature is intended to support external tools that might wish to avoid the overhead of repeatedly retrieving query texts of indeterminate length. Such tools can instead cache the first query text observed for each entry themselves, since that is all `pg_stat_statements` itself does, and then retrieve query texts only as needed. Since the server stores query texts in a file, this approach may reduce physical I/O for repeated examination of the `pg_stat_statements` data.

F.47.4. Configuration Parameters

`pg_stat_statements.max` (integer)

`pg_stat_statements.max` is the maximum number of statements tracked by the module (i.e., the maximum number of rows in the `pg_stat_statements` view). If more distinct statements than that are observed, information about the least-executed statements is discarded. The number of times such information was discarded can be seen in the `pg_stat_statements_info` view. The default value is 5000. This parameter can only be set at server start.

`pg_stat_statements.track` (enum)

`pg_stat_statements.track` controls which statements are counted by the module. Specify `top` to track top-level statements (those issued directly by clients), `all` to also track nested statements (such as statements invoked within functions), or `none` to disable statement statistics collection. The default value is `top`. Only superusers can change this setting.

`pg_stat_statements.track_utility` (boolean)

`pg_stat_statements.track_utility` controls whether utility commands are tracked by the module. Utility commands are all those other than `SELECT`, `INSERT`, `UPDATE`, `DELETE`, and `MERGE`. The default value is `on`. Only superusers can change this setting.

`pg_stat_statements.track_planning` (boolean)

`pg_stat_statements.track_planning` controls whether planning operations and duration are tracked by the module. Enabling this parameter may incur a noticeable performance penalty, especially when statements with identical query structure are executed by many concurrent connections which compete to update a small number of `pg_stat_statements` entries. The default value is `off`. Only superusers can change this setting.

`pg_stat_statements.save` (boolean)

`pg_stat_statements.save` specifies whether to save statement statistics across server shutdowns. If it is `off` then statistics are not saved at shutdown nor reloaded at server start. The default value is `on`. This parameter can only be set in the `postgresql.conf` file or on the server command line.

The module requires additional shared memory proportional to `pg_stat_statements.max`. Note that this memory is consumed whenever the module is loaded, even if `pg_stat_statements.track` is set to `none`.

These parameters must be set in `postgresql.conf`. Typical usage might be:

```
# postgresql.conf
shared_preload_libraries = 'pg_stat_statements'

compute_query_id = on
pg_stat_statements.max = 10000
pg_stat_statements.track = all
```

F.47.5. Sample Output

```
bench=# SELECT pg_stat_statements_reset();

$ pgbench -i bench
$ pgbench -c10 -t300 bench

bench=# \x
bench=# SELECT query, calls, total_exec_time, rows, 100.0 * shared_blks_hit /

F.47.6. Authors

Takahiro Itagaki <itagaki.takahiro@oss.ntt.co.jp>. Query normalization added by Peter Geoghegan <peter@2ndquadrant.com>.

F.48. pgstattuple — obtain tuple-level statistics

The `pgstattuple` module provides various functions to obtain tuple-level statistics.

Because these functions return detailed page-level information, access is restricted by default. By default, only the role `pg_stat_scan_tables` has `EXECUTE` privilege. Superusers of course bypass this restriction. After the extension has been installed, users may issue `GRANT` commands to change the privileges on the functions to allow others to execute them. However, it might be preferable to add those users to the `pg_stat_scan_tables` role instead.

F.48.1. Functions

`pgstattuple(regclass)` returns record

`pgstattuple` returns a relation's physical length, percentage of “dead” tuples, and other info. This may help users to determine whether vacuum is necessary or not. The argument is the target relation's name (optionally schema-qualified) or OID. For example:

```
test=> SELECT * FROM pgstattuple('pg_catalog.pg_proc');
-[ RECORD 1 ]-----+-----
table_len          | 458752
tuple_count        | 1470
tuple_len          | 438896
tuple_percent      | 95.67
dead_tuple_count   | 11
dead_tuple_len     | 3157
dead_tuple_percent | 0.69
free_space         | 8932
free_percent       | 1.95
```

The output columns are described in [Table F.29](#).

Table F.29. `pgstattuple` Output Columns

Column	Type	Description
<code>table_len</code>	<code>bigint</code>	Physical relation length in bytes
<code>tuple_count</code>	<code>bigint</code>	Number of live tuples
<code>tuple_len</code>	<code>bigint</code>	Total length of live tuples in bytes
<code>tuple_percent</code>	<code>float8</code>	Percentage of live tuples
<code>dead_tuple_count</code>	<code>bigint</code>	Number of dead tuples
<code>dead_tuple_len</code>	<code>bigint</code>	Total length of dead tuples in bytes
<code>dead_tuple_percent</code>	<code>float8</code>	Percentage of dead tuples
<code>free_space</code>	<code>bigint</code>	Total free space in bytes
<code>free_percent</code>	<code>float8</code>	Percentage of free space

Note

The `table_len` will always be greater than the sum of the `tuple_len`, `dead_tuple_len` and `free_space`. The difference is accounted for by fixed page overhead, the per-page table of pointers to tuples, and padding to ensure that tuples are correctly aligned.

`pgstattuple` acquires only a read lock on the relation. So the results do not reflect an instantaneous snapshot; concurrent updates will affect them.

`pgstattuple` judges a tuple is “dead” if `HeapTupleSatisfiesDirty` returns false.

`pgstattuple(text)` returns record

This is the same as `pgstattuple(regclass)`, except that the target relation is specified as TEXT. This function is kept because of backward-compatibility so far, and will be deprecated in some future release.

`pgstatindex(regclass)` returns record

`pgstatindex` returns a record showing information about a B-tree index. For example:

```
test=> SELECT * FROM pgstatindex('pg_cast_oid_index');
-[ RECORD 1 ]-----+-----
version           | 2
tree_level        | 0
index_size        | 16384
root_block_no     | 1
internal_pages    | 0
leaf_pages        | 1
empty_pages       | 0
deleted_pages     | 0
avg_leaf_density  | 54.27
leaf_fragmentation | 0
```

The output columns are:

Column	Type	Description
version	integer	B-tree version number
tree_level	integer	Tree level of the root page
index_size	bigint	Total index size in bytes
root_block_no	bigint	Location of root page (zero if none)
internal_pages	bigint	Number of “internal” (upper-level) pages
leaf_pages	bigint	Number of leaf pages
empty_pages	bigint	Number of empty pages
deleted_pages	bigint	Number of deleted pages
avg_leaf_density	float8	Average density of leaf pages
leaf_fragmentation	float8	Leaf page fragmentation

The reported `index_size` will normally correspond to one more page than is accounted for by `internal_pages` + `leaf_pages` + `empty_pages` + `deleted_pages`, because it also includes the index's metapage.

As with `pgstattuple`, the results are accumulated page-by-page, and should not be expected to represent an instantaneous snapshot of the whole index.

`pgstatindex(text)` returns record

This is the same as `pgstatindex(regclass)`, except that the target index is specified as TEXT. This function is kept because of backward-compatibility so far, and will be deprecated in some future release.

`pgstatginindex(regclass)` returns record

`pgstatginindex` returns a record showing information about a GIN index. For example:

Additional Supplied Modules
and Extensions Shipped in
postgrespro-std-16-contrib

```
test=> SELECT * FROM pgstatginindex('test_gin_index');
-[ RECORD 1 ]--+-
version      | 1
pending_pages | 0
pending_tuples | 0
```

The output columns are:

Column	Type	Description
version	integer	GIN version number
pending_pages	integer	Number of pages in the pending list
pending_tuples	bigint	Number of tuples in the pending list

`pgstathashindex(regclass)` returns record

`pgstathashindex` returns a record showing information about a HASH index. For example:

```
test=> select * from pgstathashindex('con_hash_index');
-[ RECORD 1 ]--+-
version      | 4
bucket_pages | 33081
overflow_pages | 0
bitmap_pages | 1
unused_pages | 32455
live_items   | 10204006
dead_items   | 0
free_percent  | 61.8005949100872
```

The output columns are:

Column	Type	Description
version	integer	HASH version number
bucket_pages	bigint	Number of bucket pages
overflow_pages	bigint	Number of overflow pages
bitmap_pages	bigint	Number of bitmap pages
unused_pages	bigint	Number of unused pages
live_items	bigint	Number of live tuples
dead_tuples	bigint	Number of dead tuples
free_percent	float	Percentage of free space

`pg_relpages(regclass)` returns bigint

`pg_relpages` returns the number of pages in the relation.

`pg_relpages(text)` returns bigint

This is the same as `pg_relpages(regclass)`, except that the target relation is specified as TEXT. This function is kept because of backward-compatibility so far, and will be deprecated in some future release.

`pgstattuple_approx(regclass)` returns record

`pgstattuple_approx` is a faster alternative to `pgstattuple` that returns approximate results. The argument is the target relation's name or OID. For example:

Additional Supplied Modules
and Extensions Shipped in
postgrespro-std-16-contrib

```
test=> SELECT * FROM pgstattuple_approx('pg_catalog.pg_proc'::regclass);
-[ RECORD 1 ]-----+-----
table_len          | 573440
scanned_percent    | 2
approx_tuple_count | 2740
approx_tuple_len   | 561210
approx_tuple_percent | 97.87
dead_tuple_count   | 0
dead_tuple_len     | 0
dead_tuple_percent | 0
approx_free_space  | 11996
approx_free_percent | 2.09
```

The output columns are described in [Table F.30](#).

Whereas `pgstattuple` always performs a full-table scan and returns an exact count of live and dead tuples (and their sizes) and free space, `pgstattuple_approx` tries to avoid the full-table scan and returns exact dead tuple statistics along with an approximation of the number and size of live tuples and free space.

It does this by skipping pages that have only visible tuples according to the visibility map (if a page has the corresponding VM bit set, then it is assumed to contain no dead tuples). For such pages, it derives the free space value from the free space map, and assumes that the rest of the space on the page is taken up by live tuples.

For pages that cannot be skipped, it scans each tuple, recording its presence and size in the appropriate counters, and adding up the free space on the page. At the end, it estimates the total number of live tuples based on the number of pages and tuples scanned (in the same way that `VACUUM` estimates `pg_class.relpages`).

Table F.30. `pgstattuple_approx` Output Columns

Column	Type	Description
<code>table_len</code>	<code>bigint</code>	Physical relation length in bytes (exact)
<code>scanned_percent</code>	<code>float8</code>	Percentage of table scanned
<code>approx_tuple_count</code>	<code>bigint</code>	Number of live tuples (estimated)
<code>approx_tuple_len</code>	<code>bigint</code>	Total length of live tuples in bytes (estimated)
<code>approx_tuple_percent</code>	<code>float8</code>	Percentage of live tuples
<code>dead_tuple_count</code>	<code>bigint</code>	Number of dead tuples (exact)
<code>dead_tuple_len</code>	<code>bigint</code>	Total length of dead tuples in bytes (exact)
<code>dead_tuple_percent</code>	<code>float8</code>	Percentage of dead tuples
<code>approx_free_space</code>	<code>bigint</code>	Total free space in bytes (estimated)
<code>approx_free_percent</code>	<code>float8</code>	Percentage of free space

In the above output, the free space figures may not match the `pgstattuple` output exactly, because the free space map gives us an exact figure, but is not guaranteed to be accurate to the byte.

F.49. pg_surgery — perform low-level surgery on relation data

The `pg_surgery` module provides various functions to perform surgery on a damaged relation. These functions are unsafe by design and using them may corrupt (or further corrupt) your database. For example, these functions can easily be used to make a table inconsistent with its own indexes, to cause `UNIQUE` or `FOREIGN KEY` constraint violations, or even to make tuples visible which, when read, will cause a database server crash. They should be used with great caution and only as a last resort.

F.49.1. Functions

`heap_force_kill(regclass, tid[])` returns void

`heap_force_kill` marks “used” line pointers as “dead” without examining the tuples. The intended use of this function is to forcibly remove tuples that are not otherwise accessible. For example:

```
test=> select * from t1 where ctid = '(0, 1)';
ERROR:  could not access status of transaction 4007513275
DETAIL:  Could not open file "pg_xact/0EED": No such file or directory.
```

```
test=# select heap_force_kill('t1'::regclass, ARRAY['(0, 1)']::tid[]);
 heap_force_kill
```

(1 row)

```
test=# select * from t1 where ctid = '(0, 1)';
(0 rows)
```

`heap_force_freeze(regclass, tid[])` returns void

`heap_force_freeze` marks tuples as frozen without examining the tuple data. The intended use of this function is to make accessible tuples which are inaccessible due to corrupted visibility information, or which prevent the table from being successfully vacuumed due to corrupted visibility information. For example:

```
test=> vacuum t1;
ERROR:  found xmin 507 from before relfrozenxid 515
CONTEXT:  while scanning block 0 of relation "public.t1"
```

```
test=# select ctid from t1 where xmin = 507;
 ctid
```

(0,3)

(1 row)

```
test=# select heap_force_freeze('t1'::regclass, ARRAY['(0, 3)']::tid[]);
 heap_force_freeze
```

(1 row)

```
test=# select ctid from t1 where xmin = 2;
 ctid
```

(0,3)

(1 row)

Ashutosh Sharma <ashu.coek88@gmail.com>

F.50. pg_trgm — support for similarity of text using trigram matching

The `pg_trgm` module provides functions and operators for determining the similarity of alphanumeric text based on trigram matching, as well as index operator classes that support fast searching for similar strings.

This module is considered “trusted”, that is, it can be installed by non-superusers who have `CREATE` privilege on the current database.

F.50.1. Trigram (or Trigraph) Concepts

A trigram is a group of three consecutive characters taken from a string. We can measure the similarity of two strings by counting the number of trigrams they share. This simple idea turns out to be very effective for measuring the similarity of words in many natural languages.

Note

`pg_trgm` ignores non-word characters (non-alphanumerics) when extracting trigrams from a string. Each word is considered to have two spaces prefixed and one space suffixed when determining the set of trigrams contained in the string. For example, the set of trigrams in the string “cat” is “ c”, “ ca”, “cat”, and “at ”. The set of trigrams in the string “foo|bar” is “ f”, “ fo”, “foo”, “oo ”, “ b”, “ ba”, “bar”, and “ar ”.

F.50.2. Functions and Operators

The functions provided by the `pg_trgm` module are shown in [Table F.31](#), the operators in [Table F.32](#).

Table F.31. pg_trgm Functions

Function	Description
<code>similarity (text, text) → real</code>	Returns a number that indicates how similar the two arguments are. The range of the result is zero (indicating that the two strings are completely dissimilar) to one (indicating that the two strings are identical).
<code>show_trgm (text) → text[]</code>	Returns an array of all the trigrams in the given string. (In practice this is seldom useful except for debugging.)
<code>word_similarity (text, text) → real</code>	Returns a number that indicates the greatest similarity between the set of trigrams in the first string and any continuous extent of an ordered set of trigrams in the second string. For details, see the explanation below.
<code>strict_word_similarity (text, text) → real</code>	Same as <code>word_similarity</code> , but forces extent boundaries to match word boundaries. Since we don't have cross-word trigrams, this function actually returns greatest similarity between first string and any continuous extent of words of the second string.
<code>show_limit () → real</code>	Returns the current similarity threshold used by the <code>%</code> operator. This sets the minimum similarity between two words for them to be considered similar enough to be misspellings of each other, for example. (<i>Deprecated</i> ; instead use <code>SHOW pg_trgm.similarity_threshold</code> .)
<code>set_limit (real) → real</code>	

Function	Description
	Sets the current similarity threshold that is used by the % operator. The threshold must be between 0 and 1 (default is 0.3). Returns the same value passed in. (<i>Deprecated</i> ; instead use <code>SET pg_trgm.similarity_threshold</code> .)

Consider the following example:

```
# SELECT word_similarity('word', 'two words');
word_similarity
-----
0.8
(1 row)
```

In the first string, the set of trigrams is {" w", " wo", "wor", "ord", "rd "}. In the second string, the ordered set of trigrams is {" t", " tw", "two", "wo ", " w", " wo", "wor", "ord", "rds", "ds "}. The most similar extent of an ordered set of trigrams in the second string is {" w", " wo", "wor", "ord"}, and the similarity is 0.8.

This function returns a value that can be approximately understood as the greatest similarity between the first string and any substring of the second string. However, this function does not add padding to the boundaries of the extent. Thus, the number of additional characters present in the second string is not considered, except for the mismatched word boundaries.

At the same time, `strict_word_similarity` selects an extent of words in the second string. In the example above, `strict_word_similarity` would select the extent of a single word 'words', whose set of trigrams is {" w", " wo", "wor", "ord", "rds", "ds "}.

```
# SELECT strict_word_similarity('word', 'two words'), similarity('word', 'words');
strict_word_similarity | similarity
-----+-----
0.571429 | 0.571429
(1 row)
```

Thus, the `strict_word_similarity` function is useful for finding the similarity to whole words, while `word_similarity` is more suitable for finding the similarity for parts of words.

Table F.32. pg_trgm Operators

Operator	Description
<code>text % text → boolean</code>	Returns <code>true</code> if its arguments have a similarity that is greater than the current similarity threshold set by <code>pg_trgm.similarity_threshold</code> .
<code>text <% text → boolean</code>	Returns <code>true</code> if the similarity between the trigram set in the first argument and a continuous extent of an ordered trigram set in the second argument is greater than the current word similarity threshold set by <code>pg_trgm.word_similarity_threshold</code> parameter.
<code>text %> text → boolean</code>	Commutator of the <code><%</code> operator.
<code>text <<% text → boolean</code>	Returns <code>true</code> if its second argument has a continuous extent of an ordered trigram set that matches word boundaries, and its similarity to the trigram set of the first argument is greater than the current strict word similarity threshold set by the <code>pg_trgm.strict_word_similarity_threshold</code> parameter.
<code>text %>> text → boolean</code>	

Operator	Description
	Commutator of the <<% operator.
<code>text <-> text → real</code>	Returns the “distance” between the arguments, that is one minus the <code>similarity()</code> value.
<code>text <<-> text → real</code>	Returns the “distance” between the arguments, that is one minus the <code>word_similarity()</code> value.
<code>text <->> text → real</code>	Commutator of the <<-> operator.
<code>text <<<-> text → real</code>	Returns the “distance” between the arguments, that is one minus the <code>strict_word_similarity()</code> value.
<code>text <->>> text → real</code>	Commutator of the <<<-> operator.

F.50.3. GUC Parameters

`pg_trgm.similarity_threshold (real)`

Sets the current similarity threshold that is used by the % operator. The threshold must be between 0 and 1 (default is 0.3).

`pg_trgm.word_similarity_threshold (real)`

Sets the current word similarity threshold that is used by the <% and %> operators. The threshold must be between 0 and 1 (default is 0.6).

`pg_trgm.strict_word_similarity_threshold (real)`

Sets the current strict word similarity threshold that is used by the <<% and %>> operators. The threshold must be between 0 and 1 (default is 0.5).

F.50.4. Index Support

The `pg_trgm` module provides GiST and GIN index operator classes that allow you to create an index over a text column for the purpose of very fast similarity searches. These index types support the above-described similarity operators, and additionally support trigram-based index searches for `LIKE`, `ILIKE`, `~`, `~*` and `=` queries. The similarity comparisons are case-insensitive in a default build of `pg_trgm`. Inequality operators are not supported. Note that those indexes may not be as efficient as regular B-tree indexes for equality operator.

Example:

```
CREATE TABLE test_trgm (t text);
CREATE INDEX trgm_idx ON test_trgm USING GIST (t gist_trgm_ops);
```

or

```
CREATE INDEX trgm_idx ON test_trgm USING GIN (t gin_trgm_ops);
```

`gist_trgm_ops` GiST opclass approximates a set of trigrams as a bitmap signature. Its optional integer parameter `siglen` determines the signature length in bytes. The default length is 12 bytes. Valid values of signature length are between 1 and 2024 bytes. Longer signatures lead to a more precise search (scanning a smaller fraction of the index and fewer heap pages), at the cost of a larger index.

Example of creating such an index with a signature length of 32 bytes:

```
CREATE INDEX trgm_idx ON test_trgm USING GIST (t gist_trgm_ops(siglen=32));
```

At this point, you will have an index on the `t` column that you can use for similarity searching. A typical query is

```
SELECT t, similarity(t, 'word') AS sml
FROM test_trgm
WHERE t % 'word'
ORDER BY sml DESC, t;
```

This will return all values in the text column that are sufficiently similar to *word*, sorted from best match to worst. The index will be used to make this a fast operation even over very large data sets.

A variant of the above query is

```
SELECT t, t <-> 'word' AS dist
FROM test_trgm
ORDER BY dist LIMIT 10;
```

This can be implemented quite efficiently by GiST indexes, but not by GIN indexes. It will usually beat the first formulation when only a small number of the closest matches is wanted.

Also you can use an index on the `t` column for word similarity or strict word similarity. Typical queries are:

```
SELECT t, word_similarity('word', t) AS sml
FROM test_trgm
WHERE 'word' <% t
ORDER BY sml DESC, t;
```

and

```
SELECT t, strict_word_similarity('word', t) AS sml
FROM test_trgm
WHERE 'word' <<% t
ORDER BY sml DESC, t;
```

This will return all values in the text column for which there is a continuous extent in the corresponding ordered trigram set that is sufficiently similar to the trigram set of *word*, sorted from best match to worst. The index will be used to make this a fast operation even over very large data sets.

Possible variants of the above queries are:

```
SELECT t, 'word' <<-> t AS dist
FROM test_trgm
ORDER BY dist LIMIT 10;
```

and

```
SELECT t, 'word' <<<-> t AS dist
FROM test_trgm
ORDER BY dist LIMIT 10;
```

This can be implemented quite efficiently by GiST indexes, but not by GIN indexes.

Beginning in PostgreSQL 9.1, these index types also support index searches for `LIKE` and `ILIKE`, for example

```
SELECT * FROM test_trgm WHERE t LIKE '%foo%bar';
```

The index search works by extracting trigrams from the search string and then looking these up in the index. The more trigrams in the search string, the more effective the index search is. Unlike B-tree based searches, the search string need not be left-anchored.

Beginning in PostgreSQL 9.3, these index types also support index searches for regular-expression matches (`~` and `~*` operators), for example

```
SELECT * FROM test_trgm WHERE t ~ '(foo|bar)';
```

The index search works by extracting trigrams from the regular expression and then looking these up in the index. The more trigrams that can be extracted from the regular expression, the more effective the index search is. Unlike B-tree based searches, the search string need not be left-anchored.

For both `LIKE` and regular-expression searches, keep in mind that a pattern with no extractable trigrams will degenerate to a full-index scan.

The choice between GiST and GIN indexing depends on the relative performance characteristics of GiST and GIN, which are discussed elsewhere.

F.50.5. Text Search Integration

Trigram matching is a very useful tool when used in conjunction with a full text index. In particular it can help to recognize misspelled input words that will not be matched directly by the full text search mechanism.

The first step is to generate an auxiliary table containing all the unique words in the documents:

```
CREATE TABLE words AS SELECT word FROM
    ts_stat('SELECT to_tsvector(''simple'', bodytext) FROM documents');
```

where `documents` is a table that has a text field `bodytext` that we wish to search. The reason for using the `simple` configuration with the `to_tsvector` function, instead of using a language-specific configuration, is that we want a list of the original (unstemmed) words.

Next, create a trigram index on the word column:

```
CREATE INDEX words_idx ON words USING GIN (word gin_trgm_ops);
```

Now, a `SELECT` query similar to the previous example can be used to suggest spellings for misspelled words in user search terms. A useful extra test is to require that the selected words are also of similar length to the misspelled word.

Note

Since the `words` table has been generated as a separate, static table, it will need to be periodically regenerated so that it remains reasonably up-to-date with the document collection. Keeping it exactly current is usually unnecessary.

F.51. pg_tsparser — an extension for text search

pg_tsparser is a Postgres Pro extension for text search. This extension modifies the default text parsing strategy for words that include:

- underscores
- numbers and letters separated by the hyphen character

In addition to separate word parts returned by default, pg_tsparser also returns the whole word.

F.51.1. Installation and Setup

pg_tsparser is included into the Postgres Pro distribution. To enable pg_tsparser, once Postgres Pro is installed, create the pg_tsparser extension for each database you are planning to use:

```
CREATE EXTENSION pg_tsparser;
```

Once pg_tsparser is enabled, you can create your own text search configuration. In addition to pg_tsparser, you can use any available dictionary.

For example, you can create english_ts configuration for the English language, as follows:

```
CREATE TEXT SEARCH CONFIGURATION english_ts (  
    PARSER = tsparser  
);
```

```
COMMENT ON TEXT SEARCH CONFIGURATION english_ts IS 'text search configuration for  
english language';
```

```
ALTER TEXT SEARCH CONFIGURATION english_ts  
    ADD MAPPING FOR email, file, float, host, hword_numpart, int,  
    numhword, numword, sfloat, uint, url, url_path, version  
    WITH simple;
```

```
ALTER TEXT SEARCH CONFIGURATION english_ts  
    ADD MAPPING FOR asciiword, asciihword, hword_asciipart,  
    word, hword, hword_part  
    WITH english_stem;
```

F.51.2. Examples

The following examples illustrate the difference in search results returned by pg_tsparser and the default parser:

```
SELECT to_tsvector('english', 'pg_trgm') as def_parser,  
       to_tsvector('english_ts', 'pg_trgm') as new_parser;  
def_parser | new_parser  
-----+-----  
'pg':1 'trgm':2 | 'pg':2 'pg_trgm':1 'trgm':3  
(1 row)
```

```
SELECT to_tsvector('english', '123-abc') as def_parser,  
       to_tsvector('english_ts', '123-abc') as new_parser;  
def_parser | new_parser  
-----+-----  
'123':1 'abc':2 | '123':2 '123-abc':1 'abc':3  
(1 row)
```

```
SELECT to_tsvector('english', 'rel-3.2-A') as def_parser,  
       to_tsvector('english_ts', 'rel-3.2-A') as new_parser;
```

Additional Supplied Modules
and Extensions Shipped in
postgrespro-std-16-contrib

def_parser	new_parser
-----+-----	
'-3.2':2 'rel':1 '3.2':3 'rel':2 'rel-3.2-a':1	
(1 row)

F.52. pg_variables — functions for working with variables of various types

The `pg_variables` module provides functions for working with variables of various types. The created variables are only available in the current user session.

F.52.1. Installation

The `pg_variables` extension is included into Postgres Pro. Once you have Postgres Pro installed, you must execute the `CREATE EXTENSION` command to enable `pg_variables`, as follows:

```
CREATE EXTENSION pg_variables;
```

F.52.2. Usage

The `pg_variables` module provides several functions for creating, reading, and managing variables of scalar, record, and array types. See the following sections for function descriptions and syntax:

- [Section F.52.3.1](#) describes functions for scalar variables.
- [Section F.52.3.2](#) describes functions for collections of record variables.
- [Section F.52.3.3](#) describes functions for array variables.
- [Section F.52.3.4](#) describes functions for general collection variables.
- [Section F.52.3.5](#) describes functions for using iterators to traverse collection variables.
- [Section F.52.3.6](#) lists functions you can use to manage all variables in your current session.

For detailed usage examples, see [Section F.52.5](#).

F.52.2.1. Using Transactional Variables

By default, the created variables are non-transactional. Once successfully set, a variable exists for the whole session, regardless of rollbacks, if any. For example:

```
SELECT pgv_set('vars', 'int1', 101);
BEGIN;
SELECT pgv_set('vars', 'int2', 102);
ROLLBACK;

SELECT * FROM pgv_list() order by package, name;
 package | name | is_transactional
-----+-----+-----
 vars    | int1 | f
 vars    | int2 | f
```

If you would like to use variables that support transactions and savepoints, pass the optional `is_transactional` flag as the last parameter when creating this variable:

```
BEGIN;
SELECT pgv_set('vars', 'trans_int', 101, true);
SAVEPOINT sp1;
SELECT pgv_set('vars', 'trans_int', 102, true);
ROLLBACK TO sp1;
COMMIT;
SELECT pgv_get('vars', 'trans_int', NULL::int);
 pgv_get
-----
      101
```

You must use the `is_transactional` flag every time you change the value of a transactional variable using `pgv_set()` or `pgv_insert()` functions. Otherwise, an error occurs. Other functions do not require this flag.

```
SELECT pgv_insert('pack', 'var_record', row(123::int, 'text'::text), true);
```

```
SELECT pgv_insert('pack', 'var_record', row(456::int, 'another text'::text));
ERROR:  variable "var_record" already created as TRANSACTIONAL
```

```
SELECT pgv_delete('pack', 'var_record', 123::int);
```

If the `pgv_free()` or `pgv_remove()` function calls are rolled back, the affected transactional variables will be restored, unlike non-transactional variables, which are removed permanently. For example:

```
SELECT pgv_set('pack', 'var_reg', 123);
SELECT pgv_set('pack', 'var_trans', 456, true);
BEGIN;
SELECT pgv_free();
ROLLBACK;
SELECT * FROM pgv_list();
 package |      name      | is_transactional
-----+-----+-----
 pack    | var_trans      | t
```

F.52.3. Functions

F.52.3.1. Scalar Variables

The following functions support scalar variables:

Function	Returns
<code>pgv_set(package text, name text, value anynonarray, is_transactional bool default false)</code>	void
<code>pgv_get(package text, name text, var_type anynonarray, strict bool default true)</code>	anynonarray

To use the `pgv_get()` function, you must first create a package and a variable using the `pgv_set()` function. If the specified package or variable does not exist, an error occurs:

```
SELECT pgv_get('vars', 'int1', NULL::int);
ERROR:  unrecognized package "vars"
```

```
SELECT pgv_get('vars', 'int1', NULL::int);
ERROR:  unrecognized variable "int1"
```

`pgv_get()` function checks the variable type. If the specified type does not match the type of the variable, an error is raised:

```
SELECT pgv_get('vars', 'int1', NULL::text);
ERROR:  variable "int1" requires "integer" value
```

F.52.3.2. Collections of Records

The following functions support collections of record variables:

Function	Returns	Description
<code>pgv_insert(package text, name text, r record, is_transactional bool default false)</code>	void	Inserts a record into a collection variable for the specified package. If the package or variable does not exist, it is created automatically. The first column of <code>r</code> is the primary key. If a record with the same primary key already exists or this collection variable

Additional Supplied Modules
and Extensions Shipped in
postgrespro-std-16-contrib

Function	Returns	Description
		has a different structure, an error is raised.
<code>pgv_update(package text, name text, r record)</code>	boolean	Updates a record with the corresponding primary key (the first column of <code>r</code> is the primary key). Returns <code>true</code> if the record was found. If this collection variable has a different structure, an error is raised.
<code>pgv_delete(package text, name text, value anynonarray)</code>	boolean	Deletes a record with the corresponding primary key (the first column of <code>r</code> is the primary key). Returns <code>true</code> if the record was found and <code>false</code> otherwise.
<code>pgv_select(package text, name text)</code>	set of records	Returns the collection variable records.
<code>pgv_select(package text, name text, value anynonarray)</code>	record	Returns the record with the corresponding primary key (the first column of <code>r</code> is a primary key).
<code>pgv_select(package text, name text, value anyarray)</code>	set of records	Returns the collection variable records with the corresponding primary keys (the first column of <code>r</code> is a primary key).

To use `pgv_update()`, `pgv_delete()` and `pgv_select()` functions, you must first create a package and a variable using the `pgv_insert()` function. The variable type and the record type must be the same; otherwise, an error occurs.

F.52.3.3. Arrays

The following functions support array variables:

Function	Returns
<code>pgv_set(package text, name text, value anyarray, is_transactional bool default false)</code>	void
<code>pgv_get(package text, name text, var_ type anyarray, strict bool default true)</code>	anyarray

Usage instructions for these functions are the same as those provided in [Section F.52.3.1](#) for scalar variables.

F.52.3.4. General Collections

The following functions support general collection variables:

Function	Returns	Description
<code>pgv_set_elem(package text, name text, key int, value anyelement, is_ transactional bool default false)</code>	void	Sets a value for the element with the key <code>key</code> of the collection variable <code>name</code> in the package <code>package</code> . If the package or variable does not exist, it is created automatically. Inside one collection, only keys of the same type are allowed. The <code>key</code> argument
<code>pgv_set_elem(package text, name text, key</code>		

Additional Supplied Modules
and Extensions Shipped in
postgrespro-std-16-contrib

Function	Returns	Description
<code>text, value anyelement, is_transactional bool de- fault false)</code>		can have either <code>int</code> or <code>text</code> type. If an element with the specified key already exists, its value is set to the new one. <code>is_transactional</code> shows whether the new variable is transactional and equals <code>false</code> by default. So if the variable already exists, it must be transactional/non-transactional as indicated by <code>is_transactional</code>, otherwise an error is raised. If the collection already exists and its value type does not match the type of the new value, an error is also raised.
<code>pgv_get_elem(package text, name text, key int, val_type anyelement)</code> <code>pgv_get_elem(package text, name text, key text, val_type anyelement)</code>	<code>anyelement</code>	Returns the value of the element with the key <code>key</code> of the collection variable <code>name</code> in the package <code>package</code>. If there is no element with the specified key in this collection, returns <code>NULL</code>. The <code>key</code> argument can have either <code>int</code> or <code>text</code> type. If the package or variable does not exist, an error is raised. If the specified variable is not a collection, an error is also raised. The <code>val_type</code> argument is required to properly determine the return type.
<code>pgv_exists_elem(package text, name text, key int)</code> <code>pgv_exists_elem(package text, name text, key text)</code>	<code>bool</code>	Returns <code>true</code> if an element with the key <code>key</code> exists in the collection variable <code>name</code> in the package <code>package</code> and <code>false</code> otherwise. If the package or variable does not exist, also returns <code>false</code>. The <code>key</code> argument can have either <code>int</code> or <code>text</code> type. If the specified variable is not a collection, an error is raised.
<code>pgv_remove_elem(package text, name text, key int)</code> <code>pgv_remove_elem(package text, name text, key text)</code>	<code>void</code>	Removes the element with the key <code>key</code> from the collection variable <code>name</code> in the package <code>package</code>. If there is no element with the specified key in this collection, does nothing. The <code>key</code> argument can have either <code>int</code> or <code>text</code> type. If the package or variable does not exist, an error is raised. If the specified variable is not a collection, an error is also raised.

Important

Collections initialized with `pgv_set_elem()` and with `pgv_insert()` are not considered compatible.

F.52.3.5. Iterators

The following functions are provided to use iterators to traverse collection variables. These functions work with collections initialized with both `pgv_set_elem()` and `pgv_insert()`.

Function	Returns	Description
<code>pgv_first(package text, name text, key_type anyelement)</code>	<code>anyelement</code>	Returns the first key from the collection variable. Collections are sorted by the key in ascending order. <code>key_type</code> is required to determine the return value. If the <code>name</code> passed is the name of a non-collection variable, an error is raised.
<code>pgv_last(package text, name text, key_type anyelement)</code>	<code>anyelement</code>	Returns the last key from the collection variable. Collections are sorted by the key in ascending order. <code>key_type</code> is required to determine the return value. If the <code>name</code> passed is the name of a non-collection variable, an error is raised.
<code>pgv_next(package text, name text, key anyelement)</code>	<code>anyelement</code>	Returns the next key from the collection variable. The <code>key</code> passed may not exist in the collection. Returns NULL if used for the last key in the collection. Collections are sorted by the key in ascending order. If the <code>name</code> passed is the name of a non-collection variable, an error is raised.
<code>pgv_prior(package text, name text, key anyelement)</code>	<code>anyelement</code>	Returns the previous key from the collection variable. The <code>key</code> passed may not exist in the collection. Returns NULL if used for the first key in the collection. Collections are sorted by the key in ascending order. If the <code>name</code> passed is the name of a non-collection variable, an error is raised.
<code>pgv_count(package text, name text)</code>	<code>integer</code>	Returns the number of elements in the collection. If the <code>name</code> passed is the name of a non-collection variable, an error is raised.

F.52.3.6. Miscellaneous Functions

Function	Returns	Description
<code>pgv_exists(package text, name text)</code>	bool	Returns <code>true</code> if the specified package and variable exist and <code>false</code> otherwise.
<code>pgv_exists(package text)</code>	bool	Returns <code>true</code> if the specified package exists and <code>false</code> otherwise.
<code>pgv_remove(package text, name text)</code>	void	Removes the variable with the specified name. The specified package and variable must exist; otherwise, an error is raised.
<code>pgv_remove(package text)</code>	void	Removes the specified package and all the corresponding variables. The specified package must exist; otherwise, an error is raised.
<code>pgv_free()</code>	void	Removes all packages and variables.
<code>pgv_list()</code>	<code>table(package text, name text, is_transactional bool)</code>	Displays all the available variables and the corresponding packages, as well as whether each variable is transactional.
<code>pgv_stats()</code>	<code>table(package text, allocated_memory bigint)</code>	Returns the list of assigned packages and the amount of memory used by variables, in bytes. If you are using transactional variables, this list also includes all deleted packages that still may be restored by a <code>ROLLBACK</code> . This function only supports Postgres Pro 9.6 or higher.

F.52.3.7. Deprecated Functions

F.52.3.7.1. Integer Variables

The following functions are deprecated. Use generic functions for [scalar variables](#) instead.

Function	Returns
<code>pgv_set_int(package text, name text, value int, is_transactional bool default false)</code>	void
<code>pgv_get_int(package text, name text, strict bool default true)</code>	int

F.52.3.7.2. Text Variables

The following functions are deprecated. Use generic functions for [scalar variables](#) instead.

Function	Returns
<code>pgv_set_text(package text, name text, value text, is_transactional bool default false)</code>	void

Function	Returns
<code>pgv_get_text(package text, name text, strict bool default true)</code>	text

F.52.3.7.3. Numeric Variables

The following functions are deprecated. Use generic functions for [scalar variables](#) instead.

Function	Returns
<code>pgv_set_numeric(package text, name text, value numeric, is_transactional bool default false)</code>	void
<code>pgv_get_numeric(package text, name text, strict bool default true)</code>	numeric

F.52.3.7.4. Timestamp Variables

The following functions are deprecated. Use generic functions for [scalar variables](#) instead.

Function	Returns
<code>pgv_set_timestamp(package text, name text, value timestamp, is_transactional bool default false)</code>	void
<code>pgv_get_timestamp(package text, name text, strict bool default true)</code>	timestamp

F.52.3.7.5. Timestamp with timezone Variables

The following functions are deprecated. Use generic functions for [scalar variables](#) instead.

Function	Returns
<code>pgv_set_timestamptz(package text, name text, value timestamptz, is_transac- tional bool default false)</code>	void
<code>pgv_get_timestamptz(package text, name text, strict bool default true)</code>	timestamptz

F.52.3.7.6. Date Variables

The following functions are deprecated. Use generic functions for [scalar variables](#) instead.

Function	Returns
<code>pgv_set_date(package text, name text, value date, is_transactional bool de- fault false)</code>	void
<code>pgv_get_date(package text, name text, strict bool default true)</code>	date

F.52.3.7.7. Jsonb Variables

The following functions are deprecated. Use generic functions for [scalar variables](#) instead.

Function	Returns
<code>pgv_set_jsonb(package text, name text, value jsonb, is_transactional bool default false)</code>	void

Function	Returns
<code>pgv_get_jsonb(package text, name text, strict bool default true)</code>	jsonb

F.52.4. Important Notes

F.52.4.1. Collations in Collections

Collections are stored in ascending order. In the case of `text` keys, you need a collation to determine the order of elements. If no collation is specified when inserting the first element of a collection, the default collation is used. Otherwise, the specified collation is used.

F.52.4.2. Cursors for Set-Returning Functions

All set-returning functions except `pgv_select(package, variable)` fix their return results at first `FETCH` from the cursor and are not affected by further data manipulation.

The results of `pgv_select(package, variable)` are received dynamically and are affected by transactions/changes in the collection. For `pgv_select()` called for a transactional collection, cursors look at the snapshot of the collection when the first `FETCH` was executed, but consider changes that were made in that transaction and in committed subtransactions.

F.52.5. Examples

Define scalar variables using the `pgv_set()` function, and then return their values using the `pgv_get()` function:

```
SELECT pgv_set('vars', 'int1', 101);
SELECT pgv_set('vars', 'int2', 102);
SELECT pgv_set('vars', 'text1', 'text variable'::text);
```

```
SELECT pgv_get('vars', 'int1', NULL::int);
pgv_get
-----
      101
```

```
SELECT pgv_get('vars', 'int2', NULL::int);
pgv_get
-----
      102
```

```
SELECT pgv_get('vars', 'text1', NULL::text);
pgv_get
-----
text variable
```

Let's assume we have the `tab` table and examine several examples of using record variables:

```
CREATE TABLE tab (id int, t varchar);
INSERT INTO tab VALUES (0, 'str00'), (1, 'str11');
```

You can use the following functions to work with record variables:

```
SELECT pgv_insert('vars', 'r1', tab) FROM tab;
```

```
SELECT pgv_select('vars', 'r1');
pgv_select
-----
(1,str11)
(0,str00)
```

```
SELECT pgv_select('vars', 'r1', 1);
pgv_select
-----
(1,str11)

SELECT pgv_select('vars', 'r1', 0);
pgv_select
-----
(0,str00)

SELECT pgv_select('vars', 'r1', ARRAY[1, 0]);
pgv_select
-----
(1,str11)
(0,str00)

SELECT pgv_delete('vars', 'r1', 1);

SELECT pgv_select('vars', 'r1');
pgv_select
-----
(0,str00)
```

Consider the behavior of a transactional variable `var_text` when changed before and after savepoints:

```
SELECT pgv_set('pack', 'var_text', 'before transaction block'::text, true);
BEGIN;
SELECT pgv_set('pack', 'var_text', 'before savepoint'::text, true);
SAVEPOINT sp1;
SELECT pgv_set('pack', 'var_text', 'savepoint sp1'::text, true);
SAVEPOINT sp2;
SELECT pgv_set('pack', 'var_text', 'savepoint sp2'::text, true);
RELEASE sp2;
SELECT pgv_get('pack', 'var_text', NULL::text);
pgv_get
-----
savepoint sp2

ROLLBACK TO sp1;
SELECT pgv_get('pack', 'var_text', NULL::text);
pgv_get
-----
before savepoint

ROLLBACK;
SELECT pgv_get('pack', 'var_text', NULL::text);
pgv_get
-----
before transaction block
```

If you create a variable after `BEGIN` or `SAVEPOINT` statements and then rollback to the previous state, the transactional variable is removed:

```
BEGIN;
SAVEPOINT sp1;
SAVEPOINT sp2;
SELECT pgv_set('pack', 'var_int', 122, true);
RELEASE SAVEPOINT sp2;
```

```
SELECT pgv_get('pack', 'var_int', NULL::int);
pgv_get
-----
      122
```

```
ROLLBACK TO sp1;
SELECT pgv_get('pack', 'var_int', NULL::int);
ERROR:  unrecognized variable "var_int"
COMMIT;
```

List the available packages and variables:

```
SELECT * FROM pgv_list() ORDER BY package, name;
 package |   name   | is_transactional
-----+-----+-----
 pack    | var_text | t
 vars    | int1     | f
 vars    | int2     | f
 vars    | r1       | f
 vars    | text1    | f
```

Get the amount of memory used by variables, in bytes:

```
SELECT * FROM pgv_stats() ORDER BY package;
 package | allocated_memory
-----+-----
 pack    |          16384
 vars    |          32768
```

Delete the specified variables or packages:

```
SELECT pgv_remove('vars', 'int1');
SELECT pgv_remove('vars');
```

Delete all packages and variables:

```
SELECT pgv_free();
```

These examples show usage of collection variables and iterator functions:

```
sql
SELECT pgv_set_elem('pack', 'var', 1, 1);
SELECT pgv_set_elem('pack', 'var', 5, 5);
SELECT pgv_set_elem('pack', 'var', 10, 10);

SELECT pgv_first('pack', 'var', NULL::int);
pgv_first
-----
      1

SELECT pgv_last('pack', 'var', NULL::int);
pgv_last
-----
     10

SELECT pgv_next('pack', 'var', pgv_first('pack', 'var', NULL::int));
pgv_next
-----
      5

SELECT pgv_prior('pack', 'var', pgv_last('pack', 'var', NULL::int));
pgv_prior
```

```

-----
5

SELECT pgv_prior('pack', 'var', pgv_first('pack', 'var', NULL::int));
pgv_prior
-----

SELECT pgv_next('pack', 'var', pgv_last('pack', 'var', NULL::int));
pgv_prior
-----

SELECT pgv_next('pack', 'var', 3);
pgv_next
-----
5

SELECT pgv_prior('pack', 'var', 3);
pgv_prior
-----
1

SELECT pgv_get_elem('pack', 'var', pgv_last('pack', 'var', NULL::int), NULL::int);
pgv_get_elem
-----
10

SELECT pgv_remove_elem('pack', 'var', pgv_last('pack', 'var', NULL::int));
pgv_remove_elem
-----

SELECT pgv_get_elem('pack', 'var', pgv_last('pack', 'var', NULL::int), NULL::int);
pgv_get_elem
-----
5
(1 row)

```

These examples show how the collation affects the order of elements in a collection. They also show how to iterate over a whole collection with PL/pgSQL loops:

```

sql
SELECT pgv_set_elem('pack', 'var1', 'a' COLLATE "ru_RU", 'a'::text);
SELECT pgv_set_elem('pack', 'var1', 'д' COLLATE "ru_RU", 'д'::text);
SELECT pgv_set_elem('pack', 'var1', 'e' COLLATE "ru_RU", 'e'::text);
SELECT pgv_set_elem('pack', 'var1', 'ë' COLLATE "ru_RU", 'ë'::text);
SELECT pgv_set_elem('pack', 'var1', 'ж' COLLATE "ru_RU", 'ж'::text);
SELECT pgv_set_elem('pack', 'var1', 'я' COLLATE "ru_RU", 'я'::text);
DO
$$
DECLARE
    iter text;
BEGIN
    iter := pgv_first('pack', 'var1', NULL::text);
    WHILE iter IS NOT NULL LOOP
        RAISE NOTICE '%', pgv_get_elem('pack', 'var1', iter, NULL::text);
        iter := pgv_next('pack', 'var1', iter);
    END LOOP;
END;
$$;

```

F.53. pg_visibility — visibility map information and utilities

The `pg_visibility` module provides a means for examining the visibility map (VM) and page-level visibility information of a table. It also provides functions to check the integrity of a visibility map and to force it to be rebuilt.

Three different bits are used to store information about page-level visibility. The all-visible bit in the visibility map indicates that every tuple in the corresponding page of the relation is visible to every current and future transaction. The all-frozen bit in the visibility map indicates that every tuple in the page is frozen; that is, no future vacuum will need to modify the page until such time as a tuple is inserted, updated, deleted, or locked on that page. The page header's `PD_ALL_VISIBLE` bit has the same meaning as the all-visible bit in the visibility map, but is stored within the data page itself rather than in a separate data structure. These two bits will normally agree, but the page's all-visible bit can sometimes be set while the visibility map bit is clear after a crash recovery. The reported values can also disagree because of a change that occurs after `pg_visibility` examines the visibility map and before it examines the data page. Any event that causes data corruption can also cause these bits to disagree.

Functions that display information about `PD_ALL_VISIBLE` bits are much more costly than those that only consult the visibility map, because they must read the relation's data blocks rather than only the (much smaller) visibility map. Functions that check the relation's data blocks are similarly expensive.

F.53.1. Functions

`pg_visibility_map(relation regclass, blkno bigint, all_visible OUT boolean, all_frozen OUT boolean)` returns record

Returns the all-visible and all-frozen bits in the visibility map for the given block of the given relation.

`pg_visibility(relation regclass, blkno bigint, all_visible OUT boolean, all_frozen OUT boolean, pd_all_visible OUT boolean)` returns record

Returns the all-visible and all-frozen bits in the visibility map for the given block of the given relation, plus the `PD_ALL_VISIBLE` bit of that block.

`pg_visibility_map(relation regclass, blkno OUT bigint, all_visible OUT boolean, all_frozen OUT boolean)` returns setof record

Returns the all-visible and all-frozen bits in the visibility map for each block of the given relation.

`pg_visibility(relation regclass, blkno OUT bigint, all_visible OUT boolean, all_frozen OUT boolean, pd_all_visible OUT boolean)` returns setof record

Returns the all-visible and all-frozen bits in the visibility map for each block of the given relation, plus the `PD_ALL_VISIBLE` bit of each block.

`pg_visibility_map_summary(relation regclass, all_visible OUT bigint, all_frozen OUT bigint)` returns record

Returns the number of all-visible pages and the number of all-frozen pages in the relation according to the visibility map.

`pg_check_frozen(relation regclass, t_ctid OUT tid)` returns setof tid

Returns the TIDs of non-frozen tuples stored in pages marked all-frozen in the visibility map. If this function returns a non-empty set of TIDs, the visibility map is corrupt.

`pg_check_visible(relation regclass, t_ctid OUT tid)` returns setof tid

Returns the TIDs of non-all-visible tuples stored in pages marked all-visible in the visibility map. If this function returns a non-empty set of TIDs, the visibility map is corrupt.

`pg_truncate_visibility_map(relation regclass)` returns void

Truncates the visibility map for the given relation. This function is useful if you believe that the visibility map for the relation is corrupt and wish to force rebuilding it. The first `VACUUM` executed on the given relation after this function is executed will scan every page in the relation and rebuild the visibility map. (Until that is done, queries will treat the visibility map as containing all zeroes.)

By default, these functions are executable only by superusers and roles with privileges of the `pg_stat_scan_tables` role, with the exception of `pg_truncate_visibility_map(relation regclass)` which can only be executed by superusers.

Robert Haas <rhaas@postgresql.org>

F.54. pg_wait_sampling — collecting sampling-based statistics on wait events

`pg_wait_sampling` is a Postgres Pro extension for collecting sampling-based statistics on wait events.

Starting from the 9.6 version, Postgres Pro Standard provides information about the current wait events for particular processes. However, to get descriptive statistics of the server activity, you have to sample wait events multiple times. The `pg_wait_sampling` extension automates wait events sampling by launching a special background worker. With `pg_wait_sampling` enabled, you can get the following sampling-based data:

- *Waits history* — the list of wait events for recent processes, with timestamps.
- *Waits profile* — the number of wait event samples for all processes over time (per wait event type).
- Current wait events for all processes, including background workers.

Using `pg_wait_sampling`, you can troubleshoot dependencies for queries that process longer than expected. You can see what a particular process is waiting for at each moment of time, and analyze wait events statistics. For the list of possible wait events, see [Table 26.4](#).

In combination with `pg_stat_statements`, this extension can also provide per query statistics.

See Also

[Viewing Statistics on Wait Events](#)

[Reference](#)

F.54.1. Installation

The `pg_wait_sampling` extension is included into Postgres Pro Standard and requires no special prerequisites.

To enable `pg_wait_sampling`, do the following:

1. Add `pg_wait_sampling` to the `shared_preload_libraries` variable in the `postgresql.conf` file:

```
shared_preload_libraries = 'pg_wait_sampling'
```

Important

When using the `pg_wait_sampling` with the `pg_stat_statements` extension, place `pg_stat_statements` before `pg_wait_sampling` in the `shared_preload_libraries` variable. This ensures that the `pg_stat_statements` extension does not overwrite query IDs that are used by `pg_wait_sampling`.

2. Create the `pg_wait_sampling` extension using the following query:

```
CREATE EXTENSION pg_wait_sampling;
```

3. Restart the server. Since `pg_wait_sampling` requires additional shared memory and launches a background worker, you must restart the server after adding or removing `pg_wait_sampling`.

Once the extension is created, `pg_wait_sampling` starts collecting statistics on wait events for each process. Optionally, you can change the sampling frequency and configure statistics collection modes using [GUC variables](#).

If you want to stop collecting statistics, drop the `pg_wait_sampling` extension, remove the `pg_wait_sampling` from the `shared_preload_libraries` variable, and restart the server again.

F.54.2. Usage

F.54.2.1. Viewing Statistics on Wait Events

When `pg_wait_sampling` is enabled, wait events are sampled each 10ms by default. You can access the collected statistics through a set of functions and views. If some of your queries appear stalled or take longer than expected, you can review all the current wait events in the `pg_wait_sampling_current` view:

```
SELECT * FROM pg_wait_sampling_current;
```

The returned statistics covers all the active processes, including background workers. To filter the view for a single process, run `pg_wait_sampling_get_current()` function specifying the process ID:

```
SELECT * FROM pg_wait_sampling_get_current(pid);
```

To better understand the dynamics of the recent wait events, you can access the `pg_wait_sampling_history` view that provides the wait events history for the latest processes:

```
SELECT * FROM pg_wait_sampling_history;
```

The returned view displays wait samples per process, with event timestamps. Waits history is implemented as an in-memory ring buffer. By default, the history size is limited to 5000 samples. To save history for a longer period of time, you can modify the `pg_wait_sampling.history_size` variable, or connect a client application to periodically read waits history and dump it to a local storage.

To monitor wait events in your database over time, use the `pg_wait_sampling_profile` view:

```
SELECT * FROM pg_wait_sampling_profile;
```

Waits profile is stored as an in-memory hash table that accumulates samples per each process and each wait event. You can reset waits profile by calling the `pg_wait_sampling_reset_profile()` function. If you connect a client to your database that periodically dumps the wait events data and resets the profile, you can save and compare statistics of wait events intensity over time.

Important

Since wait sampling statistics is stored in RAM, make sure to reset the waits profile from time to time to avoid memory overflow.

If you are not interested in the distribution of wait events between processes, you can set the `pg_wait_sampling.profile_pid` variable to `false`. In this case, the `pid` value for each process is set to zero, and wait samples for all the processes are stored together.

F.54.3. Reference

F.54.3.1. GUC Variables

The `pg_wait_sampling` extension is configured with GUC variables. They are stored in the local memory and can be changed in the `postgresql.conf` file or using the `ALTER SYSTEM` command. For the changes to take effect, reload the server configuration. You can do it, for example, by calling the `pg_reload_conf()` function or executing the `pg_ctl reload` command.

`pg_wait_sampling.history_size` (int4)

Size of in-memory ring buffer for history sampling, in the number of samples.

Default: 5000

`pg_wait_sampling.history_period` (int4)

Time interval for history sampling, in milliseconds.

Default: 10

`pg_wait_sampling.profile_period (int4)`

Time interval for waits profile sampling, in milliseconds.

Default: 10

`pg_wait_sampling.profile_pid (bool)`

Sampling mode for waits profile. If set to `true`, waits profile is collected per process. If you set `pg_wait_sampling.profile_pid` to `false`, waits profile is collected for all processes together. In this case, the `pid` value for each process is set to zero, and the corresponding row contains wait samples for all the processes.

Default: `true`

`pg_wait_sampling.profile_queries (enum)`

Sampling mode for the waits profile. If `pg_wait_sampling.profile_queries` is set to `none`, the `queryid` field in views will be zero. If it is set to `top`, query IDs of only the top level statements are recorded. If it is set to `all`, query IDs of nested statements are recorded. To collect the waits profile per query, ensure that the [pg_stat_statements](#) extension is configured and set `pg_wait_sampling.profile_queries` to `top`. For version 14 or higher, you can compute query IDs by configuring the `compute_query_id` parameter and set the `pg_wait_sampling.profile_queries` value to `top` or `all`. For details, see [Section 18.9.2](#).

Default: `top`

`pg_wait_sampling.sample_cpu (bool)`

The sampling mode that determines whether to perform sampling of on-CPU backends. If `pg_wait_sampling.sample_cpu` is set to `true`, then sampling also includes processes that are not waiting for anything. The wait event columns for such processes will have a `NULL` value.

Default: `true`

F.54.3.2. pg_wait_sampling Views

F.54.3.2.1. pg_wait_sampling_current View

The `pg_wait_sampling_current` view provides the information about the current wait events for all processes, including background workers.

Table F.33. pg_wait_sampling_current View

Column Name	Column Type	Description
<code>pid</code>	<code>int4</code>	Process ID
<code>event_type</code>	<code>text</code>	Name of wait event type
<code>event</code>	<code>text</code>	Name of wait event
<code>queryid</code>	<code>int8</code>	Query ID

F.54.3.2.2. pg_wait_sampling_history View

The `pg_wait_sampling_history` view provides the history of wait events. This data is stored as an in-memory ring buffer.

Table F.34. pg_wait_sampling_history View

Column Name	Column Type	Description
<code>pid</code>	<code>int4</code>	Process ID

Column Name	Column Type	Description
ts	timestampz	Sample timestamp
event_type	text	Name of wait event type
event	text	Name of wait event
queryid	int8	Query ID

F.54.3.2.3. `pg_wait_sampling_profile` View

The `pg_wait_sampling_profile` view provides the profile of wait events. This data is stored as an in-memory hash table.

Table F.35. `pg_wait_sampling_profile` View

Column Name	Column Type	Description
pid	int4	Process ID
event_type	text	Name of wait event type
event	text	Name of wait event
queryid	int8	Query ID
count	int8	Number of samples

F.54.3.3. Functions

`pg_wait_sampling_get_current(pid int4)`

Returns the `pg_wait_sampling_current` view with the list of current wait events. If you set the `pid` argument, the view is filtered for the process with this `pid`.

Arguments:

- `pid` — Optional. The process ID for which to display the current wait events.

`pg_wait_sampling_reset_profile()`

Resets the waits profile and clears the memory.

F.55. pg_walinspect — low-level WAL inspection

The `pg_walinspect` module provides SQL functions that allow you to inspect the contents of write-ahead log of a running Postgres Pro database cluster at a low level, which is useful for debugging, analytical, reporting or educational purposes. It is similar to `pg_waldump`, but accessible through SQL rather than a separate utility.

All the functions of this module will provide the WAL information using the server's current timeline ID.

Note

The `pg_walinspect` functions are often called using an LSN argument that specifies the location at which a known WAL record of interest *begins*. However, some functions, such as `pg_logical_emit_message`, return the LSN *after* the record that was just inserted.

Tip

All of the `pg_walinspect` functions that show information about records that fall within a certain LSN range are permissive about accepting `end_lsn` arguments that are after the server's current LSN. Using an `end_lsn` “from the future” will not raise an error.

It may be convenient to provide the value `FFFFFFFF/FFFFFFFF` (the maximum valid `pg_lsn` value) as an `end_lsn` argument. This is equivalent to providing an `end_lsn` argument matching the server's current LSN.

By default, use of these functions is restricted to superusers and members of the `pg_read_server_files` role. Access may be granted by superusers to others using `GRANT`.

F.55.1. General Functions

`pg_get_wal_record_info(in_lsn pg_lsn)` returns record

Gets WAL record information about a record that is located at or after the `in_lsn` argument. For example:

```
postgres=# SELECT * FROM pg_get_wal_record_info('0/E419E28');
-[ RECORD 1 ]-----+-----
start_lsn      | 0/E419E28
end_lsn        | 0/E419E68
prev_lsn       | 0/E419D78
xid            | 0
resource_manager | Heap2
record_type    | VACUUM
record_length  | 58
main_data_length | 2
fpi_length     | 0
description    | nunused: 5, unused: [1, 2, 3, 4, 5]
block_ref      | blkref #0: rel 1663/16385/1249 fork main blk 364
```

If `in_lsn` isn't at the start of a WAL record, information about the next valid WAL record is shown instead. If there is no next valid WAL record, the function raises an error.

`pg_get_wal_records_info(start_lsn pg_lsn, end_lsn pg_lsn)` returns setof record

Gets information of all the valid WAL records between `start_lsn` and `end_lsn`. Returns one row per WAL record. For example:

```
postgres=# SELECT * FROM pg_get_wal_records_info('0/1E913618', '0/1E913740') LIMIT
1;
```

Additional Supplied Modules
and Extensions Shipped in
postgrespro-std-16-contrib

```
-[ RECORD 1 ]-----+-----
start_lsn      | 0/1E913618
end_lsn        | 0/1E913650
prev_lsn       | 0/1E9135A0
xid            | 0
resource_manager | Standby
record_type     | RUNNING_XACTS
record_length  | 50
main_data_length | 24
fpi_length     | 0
description    | nextXid 33775 latestCompletedXid 33774 oldestRunningXid 33775
block_ref      |
```

The function raises an error if *start_lsn* is not available.

`pg_get_wal_block_info(start_lsn pg_lsn, end_lsn pg_lsn, show_data boolean DEFAULT true)`
returns setof record

Gets information about each block reference from all the valid WAL records between *start_lsn* and *end_lsn* with one or more block references. Returns one row per block reference per WAL record. For example:

```
postgres=# SELECT * FROM pg_get_wal_block_info('0/1230278', '0/12302B8');
```

```
-[ RECORD 1 ]-----+-----
start_lsn      | 0/1230278
end_lsn        | 0/12302B8
prev_lsn       | 0/122FD40
block_id       | 0
reltablespace  | 1663
reldatabase    | 1
relfilenode    | 2658
relforknumber  | 0
relblocknumber | 11
xid            | 341
resource_manager | Btree
record_type    | INSERT_LEAF
record_length  | 64
main_data_length | 2
block_data_length | 16
block_fpi_length | 0
block_fpi_info  |
description    | off: 46
block_data     | \x00002a00070010402630000070696400
block_fpi_data  |
```

This example involves a WAL record that only contains one block reference, but many WAL records contain several block references. Rows output by `pg_get_wal_block_info` are guaranteed to have a unique combination of *start_lsn* and *block_id* values.

Much of the information shown here matches the output that `pg_get_wal_records_info` would show, given the same arguments. However, `pg_get_wal_block_info` unnests the information from each WAL record into an expanded form by outputting one row per block reference, so certain details are tracked at the block reference level rather than at the whole-record level. This structure is useful with queries that track how individual blocks changed over time. Note that records with no block references (e.g., COMMIT WAL records) will have no rows returned, so `pg_get_wal_block_info` may actually return *fewer* rows than `pg_get_wal_records_info`.

The `reltablespace`, `reldatabase`, and `relfilenode` parameters reference `pg_tablespace.oid`, `pg_database.oid`, and `pg_class.relfilenode` respectively. The `relforknumber` field is the fork number within the relation for the block reference; see `common/relpath.h` for details.

Tip

The `pg_filenode_relation` function (see [Table 9.98](#)) can help you to determine which relation was modified during original execution.

It is possible for clients to avoid the overhead of materializing block data. This may make function execution significantly faster. When `show_data` is set to `false`, `block_data` and `block_fpi_data` values are omitted (that is, the `block_data` and `block_fpi_data` OUT arguments are `NULL` for all rows returned). Obviously, this optimization is only feasible with queries where block data isn't truly required.

The function raises an error if `start_lsn` is not available.

`pg_get_wal_stats(start_lsn pg_lsn, end_lsn pg_lsn, per_record boolean DEFAULT false)`
returns `setof record`

Gets statistics of all the valid WAL records between `start_lsn` and `end_lsn`. By default, it returns one row per `resource_manager` type. When `per_record` is set to `true`, it returns one row per `record_type`. For example:

```
postgres=# SELECT * FROM pg_get_wal_stats('0/1E847D00', '0/1E84F500')
WHERE count > 0 AND
      "resource_manager/record_type" = 'Transaction'
LIMIT 1;
```

```
-[ RECORD 1 ]-----+-----
resource_manager/record_type | Transaction
count                        | 2
count_percentage             | 8
record_size                  | 875
record_size_percentage       | 41.23468426013195
fpi_size                     | 0
fpi_size_percentage          | 0
combined_size                | 875
combined_size_percentage     | 2.8634072910530795
```

The function raises an error if `start_lsn` is not available.

F.56. plantuner — hints for the planner to disable or enable indexes for query execution

The `plantuner` module provides hints for the planner that can disable or enable indexes for query execution.

F.56.1. Motivation

In some cases, it may be required to control the planner by providing hints that make the optimizer ignore some parts of its algorithm. There are many situations when a developer may want to temporarily disable specific index(es), without dropping them, or to instruct the planner to use a specific index.

This version of `plantuner` provides a possibility to hide the specified indexes from Postgres Pro planner, so it will not use them. For some workloads, Postgres Pro could be too pessimistic about newly created tables and assume that there are much more rows in a table than it actually has. If the `plantuner.fix_empty_table` GUC variable is set to `true`, `plantuner` sets to zero the number of pages/tuples of the table that has no blocks in a file.

F.56.2. GUC Variables

`plantuner.disable_index` — list of indexes invisible to planner.

`plantuner.enable_index` — list of indexes visible to planner even if they are hidden by `plantuner.disable_index`.

F.56.3. Example

To enable the module, you can either load `plantuner` shared library in a `psql` session or specify `shared_preload_libraries` option in `postgresql.conf`.

```
=# LOAD 'plantuner';
=# create table test(id int);
=# create index id_idx on test(id);
=# create index id_idx2 on test(id);
=# \d test
      Table "public.test"
  Column | Type   | Modifiers
-----+-----+-----
 id      | integer |
Indexes:
    "id_idx" btree (id)
    "id_idx2" btree (id)
=# explain select id from test where id=1;
               QUERY PLAN
-----
Bitmap Heap Scan on test  (cost=4.34..15.03 rows=12 width=4)
  Recheck Cond: (id = 1)
    -> Bitmap Index Scan on id_idx2  (cost=0.00..4.34 rows=12 width=0)
          Index Cond: (id = 1)
(4 rows)
=# set enable_seqscan=off;
=# set plantuner.disable_index='id_idx2';
=# explain select id from test where id=1;
               QUERY PLAN
-----
Bitmap Heap Scan on test  (cost=4.34..15.03 rows=12 width=4)
  Recheck Cond: (id = 1)
    -> Bitmap Index Scan on id_idx  (cost=0.00..4.34 rows=12 width=0)
          Index Cond: (id = 1)
```

```
(4 rows)
=# set plantuner.disable_index='id_idx2,id_idx';
=# explain select id from test where id=1;
               QUERY PLAN
-----
Seq Scan on test  (cost=10000000000.00..10000000040.00 rows=12 width=4)
  Filter: (id = 1)
(2 rows)
=# set plantuner.enable_index='id_idx';
=# explain select id from test where id=1;
               QUERY PLAN
-----
Bitmap Heap Scan on test  (cost=4.34..15.03 rows=12 width=4)
  Recheck Cond: (id = 1)
    -> Bitmap Index Scan on id_idx  (cost=0.00..4.34 rows=12 width=0)
        Index Cond: (id = 1)
(4 rows)
```

F.56.4. Authors

All work was done by Teodor Sigaev (teodor@sigaev.ru) and Oleg Bartunov (oleg@sai.msu.su).

The work sponsored by Nomao project (<http://www.nomao.com>).

F.57. `postgres_fdw` — access data stored in external Postgres Pro servers

The `postgres_fdw` module provides the foreign-data wrapper `postgres_fdw`, which can be used to access data stored in external Postgres Pro servers.

The functionality provided by this module overlaps substantially with the functionality of the older [dblink](#) module. But `postgres_fdw` provides more transparent and standards-compliant syntax for accessing remote tables, and can give better performance in many cases.

To prepare for remote access using `postgres_fdw`:

1. Install the `postgres_fdw` extension using [CREATE EXTENSION](#).
2. Create a foreign server object, using [CREATE SERVER](#), to represent each remote database you want to connect to. Specify connection information, except `user` and `password`, as options of the server object.
3. Create a user mapping, using [CREATE USER MAPPING](#), for each database user you want to allow to access each foreign server. Specify the remote user name and password to use as `user` and `password` options of the user mapping.
4. Create a foreign table, using [CREATE FOREIGN TABLE](#) or [IMPORT FOREIGN SCHEMA](#), for each remote table you want to access. The columns of the foreign table must match the referenced remote table. You can, however, use table and/or column names different from the remote table's, if you specify the correct remote names as options of the foreign table object.

Now you need only `SELECT` from a foreign table to access the data stored in its underlying remote table. You can also modify the remote table using `INSERT`, `UPDATE`, `DELETE`, `COPY`, or `TRUNCATE`. (Of course, the remote user you have specified in your user mapping must have privileges to do these things.)

Note that the `ONLY` option specified in `SELECT`, `UPDATE`, `DELETE` or `TRUNCATE` has no effect when accessing or modifying the remote table.

Note that `postgres_fdw` currently lacks support for `INSERT` statements with an `ON CONFLICT DO UPDATE` clause. However, the `ON CONFLICT DO NOTHING` clause is supported, provided a unique index inference specification is omitted. Note also that `postgres_fdw` supports row movement invoked by `UPDATE` statements executed on partitioned tables, but it currently does not handle the case where a remote partition chosen to insert a moved row into is also an `UPDATE` target partition that will be updated elsewhere in the same command.

It is generally recommended that the columns of a foreign table be declared with exactly the same data types, and collations if applicable, as the referenced columns of the remote table. Although `postgres_fdw` is currently rather forgiving about performing data type conversions at need, surprising semantic anomalies may arise when types or collations do not match, due to the remote server interpreting query conditions differently from the local server.

Note that a foreign table can be declared with fewer columns, or with a different column order, than its underlying remote table has. Matching of columns to the remote table is by name, not position.

F.57.1. FDW Options of `postgres_fdw`

F.57.1.1. Connection Options

A foreign server using the `postgres_fdw` foreign data wrapper can have the same options that `libpq` accepts in connection strings, as described in [Section 33.1.2](#), except that these options are not allowed or have special handling:

- `user`, `password` and `sslpassword` (specify these in a user mapping, instead, or use a service file)
- `client_encoding` (this is automatically set from the local server encoding)
- `application_name` - this may appear in *either or both* a connection and [postgres_fdw.application_name](#). If both are present, `postgres_fdw.application_name` overrides the connection setting.

Unlike `libpq`, `postgres_fdw` allows `application_name` to include “escape sequences”. See [postgres_fdw.application_name](#) for details.

- `fallback_application_name` (always set to `postgres_fdw`)
- `sslkey` and `sslcert` - these may appear in *either or both* a connection and a user mapping. If both are present, the user mapping setting overrides the connection setting.

Only superusers may create or modify user mappings with the `sslcert` or `sslkey` settings.

Non-superusers may connect to foreign servers using password authentication or with GSSAPI delegated credentials, so specify the `password` option for user mappings belonging to non-superusers where password authentication is required.

A superuser may override this check on a per-user-mapping basis by setting the user mapping option `password_required 'false'`, e.g.,

```
ALTER USER MAPPING FOR some_non_superuser SERVER loopback_nopw
OPTIONS (ADD password_required 'false');
```

To prevent unprivileged users from exploiting the authentication rights of the unix user the postgres server is running as to escalate to superuser rights, only the superuser may set this option on a user mapping.

Care is required to ensure that this does not allow the mapped user the ability to connect as superuser to the mapped database per CVE-2007-3278 and CVE-2007-6601. Don't set `password_required=false` on the `public` role. Keep in mind that the mapped user can potentially use any client certificates, `.pgpass`, `.pg_service.conf` etc. in the unix home directory of the system user the postgres server runs as. They can also use any trust relationship granted by authentication modes like `peer` or `ident` authentication.

F.57.1.2. Object Name Options

These options can be used to control the names used in SQL statements sent to the remote Postgres Pro server. These options are needed when a foreign table is created with names different from the underlying remote table's names.

`schema_name` (string)

This option, which can be specified for a foreign table, gives the schema name to use for the foreign table on the remote server. If this option is omitted, the name of the foreign table's schema is used.

`table_name` (string)

This option, which can be specified for a foreign table, gives the table name to use for the foreign table on the remote server. If this option is omitted, the foreign table's name is used.

`column_name` (string)

This option, which can be specified for a column of a foreign table, gives the column name to use for the column on the remote server. If this option is omitted, the column's name is used.

F.57.1.3. Cost Estimation Options

`postgres_fdw` retrieves remote data by executing queries against remote servers, so ideally the estimated cost of scanning a foreign table should be whatever it costs to be done on the remote server, plus some overhead for communication. The most reliable way to get such an estimate is to ask the remote server and then add something for overhead — but for simple queries, it may not be worth the cost of an additional remote query to get a cost estimate. So `postgres_fdw` provides the following options to control how cost estimation is done:

`use_remote_estimate` (boolean)

This option, which can be specified for a foreign table or a foreign server, controls whether `postgres_fdw` issues remote `EXPLAIN` commands to obtain cost estimates. A setting for a foreign table overrides any setting for its server, but only for that table. The default is `false`.

`fdw_startup_cost` (floating point)

This option, which can be specified for a foreign server, is a floating point value that is added to the estimated startup cost of any foreign-table scan on that server. This represents the additional overhead of establishing a connection, parsing and planning the query on the remote side, etc. The default value is 100.

`fdw_tuple_cost` (floating point)

This option, which can be specified for a foreign server, is a floating point value that is used as extra cost per-tuple for foreign-table scans on that server. This represents the additional overhead of data transfer between servers. You might increase or decrease this number to reflect higher or lower network delay to the remote server. The default value is 0.01.

When `use_remote_estimate` is true, `postgres_fdw` obtains row count and cost estimates from the remote server and then adds `fdw_startup_cost` and `fdw_tuple_cost` to the cost estimates. When `use_remote_estimate` is false, `postgres_fdw` performs local row count and cost estimation and then adds `fdw_startup_cost` and `fdw_tuple_cost` to the cost estimates. This local estimation is unlikely to be very accurate unless local copies of the remote table's statistics are available. Running [ANALYZE](#) on the foreign table is the way to update the local statistics; this will perform a scan of the remote table and then calculate and store statistics just as though the table were local. Keeping local statistics can be a useful way to reduce per-query planning overhead for a remote table — but if the remote table is frequently updated, the local statistics will soon be obsolete.

The following option controls how such an `ANALYZE` operation behaves:

`analyze_sampling` (string)

This option, which can be specified for a foreign table or a foreign server, determines if `ANALYZE` on a foreign table samples the data on the remote side, or reads and transfers all data and performs the sampling locally. The supported values are `off`, `random`, `system`, `bernoulli` and `auto`. `off` disables remote sampling, so all data are transferred and sampled locally. `random` performs remote sampling using the `random()` function to choose returned rows, while `system` and `bernoulli` rely on the built-in `TABLESAMPLE` methods of those names. `random` works on all remote server versions, while `TABLESAMPLE` is supported only since 9.5. `auto` (the default) picks the recommended sampling method automatically; currently it means either `bernoulli` or `random` depending on the remote server version.

F.57.1.4. Remote Execution Options

By default, only `WHERE` clauses using built-in operators and functions will be considered for execution on the remote server. Clauses involving non-built-in functions are checked locally after rows are fetched. If such functions are available on the remote server and can be relied on to produce the same results as they do locally, performance can be improved by sending such `WHERE` clauses for remote execution. This behavior can be controlled using the following option:

`extensions` (string)

This option is a comma-separated list of names of Postgres Pro extensions that are installed, in compatible versions, on both the local and remote servers. Functions and operators that are immutable and belong to a listed extension will be considered shippable to the remote server. This option can only be specified for foreign servers, not per-table.

When using the `extensions` option, *it is the user's responsibility* that the listed extensions exist and behave identically on both the local and remote servers. Otherwise, remote queries may fail or behave unexpectedly.

`fetch_size` (integer)

This option specifies the number of rows `postgres_fdw` should get in each fetch operation. It can be specified for a foreign table or a foreign server. The option specified on a table overrides an option specified for the server. The default is 100.

`batch_size` (integer)

This option specifies the number of rows `postgres_fdw` should insert in each insert operation. It can be specified for a foreign table or a foreign server. The option specified on a table overrides an option specified for the server. The default is 1.

Note the actual number of rows `postgres_fdw` inserts at once depends on the number of columns and the provided `batch_size` value. The batch is executed as a single query, and the libpq protocol (which `postgres_fdw` uses to connect to a remote server) limits the number of parameters in a single query to 65535. When the number of columns * `batch_size` exceeds the limit, the `batch_size` will be adjusted to avoid an error.

This option also applies when copying into foreign tables. In that case the actual number of rows `postgres_fdw` copies at once is determined in a similar way to the insert case, but it is limited to at most 1000 due to implementation restrictions of the `COPY` command.

F.57.1.5. Asynchronous Execution Options

`postgres_fdw` supports asynchronous execution, which runs multiple parts of an `Append` node concurrently rather than serially to improve performance. This execution can be controlled using the following option:

`async_capable` (boolean)

This option controls whether `postgres_fdw` allows foreign tables to be scanned concurrently for asynchronous execution. It can be specified for a foreign table or a foreign server. A table-level option overrides a server-level option. The default is `false`.

In order to ensure that the data being returned from a foreign server is consistent, `postgres_fdw` will only open one connection for a given foreign server and will run all queries against that server sequentially even if there are multiple foreign tables involved, unless those tables are subject to different user mappings. In such a case, it may be more performant to disable this option to eliminate the overhead associated with running queries asynchronously.

Asynchronous execution is applied even when an `Append` node contains subplan(s) executed synchronously as well as subplan(s) executed asynchronously. In such a case, if the asynchronous subplans are ones processed using `postgres_fdw`, tuples from the asynchronous subplans are not returned until after at least one synchronous subplan returns all tuples, as that subplan is executed while the asynchronous subplans are waiting for the results of asynchronous queries sent to foreign servers. This behavior might change in a future release.

F.57.1.6. Transaction Management Options

As described in the Transaction Management section, in `postgres_fdw` transactions are managed by creating corresponding remote transactions, and subtransactions are managed by creating corresponding remote subtransactions. When multiple remote transactions are involved in the current local transaction, by default `postgres_fdw` commits or aborts those remote transactions serially when the local transaction is committed or aborted. When multiple remote subtransactions are involved in the current local subtransaction, by default `postgres_fdw` commits or aborts those remote subtransactions serially when the local subtransaction is committed or aborted. Performance can be improved with the following options:

`parallel_commit` (boolean)

This option controls whether `postgres_fdw` commits, in parallel, remote transactions opened on a foreign server in a local transaction when the local transaction is committed. This setting also applies to remote and local subtransactions. This option can only be specified for foreign servers, not per-table. The default is `false`.

`parallel_abort` (boolean)

This option controls whether `postgres_fdw` aborts, in parallel, remote transactions opened on a foreign server in a local transaction when the local transaction is aborted. This setting also applies

to remote and local subtransactions. This option can only be specified for foreign servers, not per-table. The default is `false`.

If multiple foreign servers with these options enabled are involved in a local transaction, multiple remote transactions on those foreign servers are committed or aborted in parallel across those foreign servers when the local transaction is committed or aborted.

When these options are enabled, a foreign server with many remote transactions may see a negative performance impact when the local transaction is committed or aborted.

F.57.1.7. Updatability Options

By default all foreign tables using `postgres_fdw` are assumed to be updatable. This may be overridden using the following option:

`updatable (boolean)`

This option controls whether `postgres_fdw` allows foreign tables to be modified using `INSERT`, `UPDATE` and `DELETE` commands. It can be specified for a foreign table or a foreign server. A table-level option overrides a server-level option. The default is `true`.

Of course, if the remote table is not in fact updatable, an error would occur anyway. Use of this option primarily allows the error to be thrown locally without querying the remote server. Note however that the `information_schema` views will report a `postgres_fdw` foreign table to be updatable (or not) according to the setting of this option, without any check of the remote server.

F.57.1.8. Truncatability Options

By default all foreign tables using `postgres_fdw` are assumed to be truncatable. This may be overridden using the following option:

`truncatable (boolean)`

This option controls whether `postgres_fdw` allows foreign tables to be truncated using the `TRUNCATE` command. It can be specified for a foreign table or a foreign server. A table-level option overrides a server-level option. The default is `true`.

Of course, if the remote table is not in fact truncatable, an error would occur anyway. Use of this option primarily allows the error to be thrown locally without querying the remote server.

F.57.1.9. Importing Options

`postgres_fdw` is able to import foreign table definitions using [IMPORT FOREIGN SCHEMA](#). This command creates foreign table definitions on the local server that match tables or views present on the remote server. If the remote tables to be imported have columns of user-defined data types, the local server must have compatible types of the same names.

Importing behavior can be customized with the following options (given in the `IMPORT FOREIGN SCHEMA` command):

`import_collate (boolean)`

This option controls whether column `COLLATE` options are included in the definitions of foreign tables imported from a foreign server. The default is `true`. You might need to turn this off if the remote server has a different set of collation names than the local server does, which is likely to be the case if it's running on a different operating system. If you do so, however, there is a very severe risk that the imported table columns' collations will not match the underlying data, resulting in anomalous query behavior.

Even when this parameter is set to `true`, importing columns whose collation is the remote server's default can be risky. They will be imported with `COLLATE "default"`, which will select the local server's default collation, which could be different.

`import_default` (boolean)

This option controls whether column `DEFAULT` expressions are included in the definitions of foreign tables imported from a foreign server. The default is `false`. If you enable this option, be wary of defaults that might get computed differently on the local server than they would be on the remote server; `nextval()` is a common source of problems. The `IMPORT` will fail altogether if an imported default expression uses a function or operator that does not exist locally.

`import_generated` (boolean)

This option controls whether column `GENERATED` expressions are included in the definitions of foreign tables imported from a foreign server. The default is `true`. The `IMPORT` will fail altogether if an imported generated expression uses a function or operator that does not exist locally.

`import_not_null` (boolean)

This option controls whether column `NOT NULL` constraints are included in the definitions of foreign tables imported from a foreign server. The default is `true`.

Note that constraints other than `NOT NULL` will never be imported from the remote tables. Although Postgres Pro does support check constraints on foreign tables, there is no provision for importing them automatically, because of the risk that a constraint expression could evaluate differently on the local and remote servers. Any such inconsistency in the behavior of a check constraint could lead to hard-to-detect errors in query optimization. So if you wish to import check constraints, you must do so manually, and you should verify the semantics of each one carefully. For more detail about the treatment of check constraints on foreign tables, see [CREATE FOREIGN TABLE](#).

Tables or foreign tables which are partitions of some other table are imported only when they are explicitly specified in `LIMIT TO` clause. Otherwise they are automatically excluded from [IMPORT FOREIGN SCHEMA](#). Since all data can be accessed through the partitioned table which is the root of the partitioning hierarchy, importing only partitioned tables should allow access to all the data without creating extra objects.

F.57.1.10. Connection Management Options

By default, all connections that `postgres_fdw` establishes to foreign servers are kept open in the local session for re-use.

`keep_connections` (boolean)

This option controls whether `postgres_fdw` keeps the connections to the foreign server open so that subsequent queries can re-use them. It can only be specified for a foreign server. The default is `on`. If set to `off`, all connections to this foreign server will be discarded at the end of each transaction.

F.57.2. Functions

`postgres_fdw_get_connections(OUT server_name text, OUT valid boolean)` returns setof record

This function returns the foreign server names of all the open connections that `postgres_fdw` established from the local session to the foreign servers. It also returns whether each connection is valid or not. `false` is returned if the foreign server connection is used in the current local transaction but its foreign server or user mapping is changed or dropped (Note that server name of an invalid connection will be `NULL` if the server is dropped), and then such invalid connection will be closed at the end of that transaction. `true` is returned otherwise. If there are no open connections, no record is returned. Example usage of the function:

```
postgres=# SELECT * FROM postgres_fdw_get_connections() ORDER BY 1;
 server_name | valid 
-----+-----
 loopback1  | t
```

loopback2 | f

`postgres_fdw_disconnect(server_name text)` returns boolean

This function discards the open connections that are established by `postgres_fdw` from the local session to the foreign server with the given name. Note that there can be multiple connections to the given server using different user mappings. If the connections are used in the current local transaction, they are not disconnected and warning messages are reported. This function returns `true` if it disconnects at least one connection, otherwise `false`. If no foreign server with the given name is found, an error is reported. Example usage of the function:

```
postgres=# SELECT postgres_fdw_disconnect('loopback1');
postgres_fdw_disconnect
-----
t
```

`postgres_fdw_disconnect_all()` returns boolean

This function discards all the open connections that are established by `postgres_fdw` from the local session to foreign servers. If the connections are used in the current local transaction, they are not disconnected and warning messages are reported. This function returns `true` if it disconnects at least one connection, otherwise `false`. Example usage of the function:

```
postgres=# SELECT postgres_fdw_disconnect_all();
postgres_fdw_disconnect_all
-----
t
```

F.57.3. Connection Management

`postgres_fdw` establishes a connection to a foreign server during the first query that uses a foreign table associated with the foreign server. By default this connection is kept and re-used for subsequent queries in the same session. This behavior can be controlled using `keep_connections` option for a foreign server. If multiple user identities (user mappings) are used to access the foreign server, a connection is established for each user mapping.

When changing the definition of or removing a foreign server or a user mapping, the associated connections are closed. But note that if any connections are in use in the current local transaction, they are kept until the end of the transaction. Closed connections will be re-established when they are necessary by future queries using a foreign table.

Once a connection to a foreign server has been established, it's by default kept until the local or corresponding remote session exits. To disconnect a connection explicitly, `keep_connections` option for a foreign server may be disabled, or `postgres_fdw_disconnect` and `postgres_fdw_disconnect_all` functions may be used. For example, these are useful to close connections that are no longer necessary, thereby releasing connections on the foreign server.

F.57.4. Transaction Management

During a query that references any remote tables on a foreign server, `postgres_fdw` opens a transaction on the remote server if one is not already open corresponding to the current local transaction. The remote transaction is committed or aborted when the local transaction commits or aborts. Savepoints are similarly managed by creating corresponding remote savepoints.

The remote transaction uses `SERIALIZABLE` isolation level when the local transaction has `SERIALIZABLE` isolation level; otherwise it uses `REPEATABLE READ` isolation level. This choice ensures that if a query performs multiple table scans on the remote server, it will get snapshot-consistent results for all the scans. A consequence is that successive queries within a single transaction will see the same data from the remote server, even if concurrent updates are occurring on the remote server due to other activities. That behavior would be expected anyway if the local transaction uses `SERIALIZABLE` or `REPEATABLE READ`

isolation level, but it might be surprising for a `READ COMMITTED` local transaction. A future Postgres Pro release might modify these rules.

Note that it is currently not supported by `postgres_fdw` to prepare the remote transaction for two-phase commit.

F.57.5. Remote Query Optimization

`postgres_fdw` attempts to optimize remote queries to reduce the amount of data transferred from foreign servers. This is done by sending query `WHERE` clauses to the remote server for execution, and by not retrieving table columns that are not needed for the current query. To reduce the risk of misexecution of queries, `WHERE` clauses are not sent to the remote server unless they use only data types, operators, and functions that are built-in or belong to an extension that's listed in the foreign server's `extensions` option. Operators and functions in such clauses must be `IMMUTABLE` as well. For an `UPDATE` or `DELETE` query, `postgres_fdw` attempts to optimize the query execution by sending the whole query to the remote server if there are no query `WHERE` clauses that cannot be sent to the remote server, no local joins for the query, no row-level local `BEFORE` or `AFTER` triggers or stored generated columns on the target table, and no `CHECK OPTION` constraints from parent views. In `UPDATE`, expressions to assign to target columns must use only built-in data types, `IMMUTABLE` operators, or `IMMUTABLE` functions, to reduce the risk of misexecution of the query.

When `postgres_fdw` encounters a join between foreign tables on the same foreign server, it sends the entire join to the foreign server, unless for some reason it believes that it will be more efficient to fetch rows from each table individually, or unless the table references involved are subject to different user mappings. While sending the `JOIN` clauses, it takes the same precautions as mentioned above for the `WHERE` clauses.

The query that is actually sent to the remote server for execution can be examined using `EXPLAIN VERBOSE`.

F.57.6. Remote Query Execution Environment

In the remote sessions opened by `postgres_fdw`, the `search_path` parameter is set to just `pg_catalog`, so that only built-in objects are visible without schema qualification. This is not an issue for queries generated by `postgres_fdw` itself, because it always supplies such qualification. However, this can pose a hazard for functions that are executed on the remote server via triggers or rules on remote tables. For example, if a remote table is actually a view, any functions used in that view will be executed with the restricted search path. It is recommended to schema-qualify all names in such functions, or else attach `SET search_path` options (see [CREATE FUNCTION](#)) to such functions to establish their expected search path environment.

`postgres_fdw` likewise establishes remote session settings for various parameters:

- `TimeZone` is set to `UTC`
- `DateStyle` is set to `ISO`
- `IntervalStyle` is set to `postgres`
- `extra_float_digits` is set to 3 for remote servers 9.0 and newer and is set to 2 for older versions

These are less likely to be problematic than `search_path`, but can be handled with function `SET` options if the need arises.

It is *not* recommended that you override this behavior by changing the session-level settings of these parameters; that is likely to cause `postgres_fdw` to malfunction.

F.57.7. Cross-Version Compatibility

`postgres_fdw` can be used with remote servers dating back to PostgreSQL 8.3. Read-only capability is available back to 8.1. A limitation however is that `postgres_fdw` generally assumes that immutable built-in functions and operators are safe to send to the remote server for execution, if they appear in a `WHERE` clause for a foreign table. Thus, a built-in function that was added since the remote server's

release might be sent to it for execution, resulting in “function does not exist” or a similar error. This type of failure can be worked around by rewriting the query, for example by embedding the foreign table reference in a sub-SELECT with `OFFSET 0` as an optimization fence, and placing the problematic function or operator outside the sub-SELECT.

F.57.8. Configuration Parameters

`postgres_fdw.application_name` (string)

Specifies a value for [application_name](#) configuration parameter used when `postgres_fdw` establishes a connection to a foreign server. This overrides `application_name` option of the server object. Note that change of this parameter doesn't affect any existing connections until they are re-established.

`postgres_fdw.application_name` can be any string of any length and contain even non-ASCII characters. However when it's passed to and used as `application_name` in a foreign server, note that it will be truncated to less than `NAMEDATALEN` characters. Anything other than printable ASCII characters are replaced with [C-style hexadecimal escapes](#). See [application_name](#) for details.

`%` characters begin “escape sequences” that are replaced with status information as outlined below. Unrecognized escapes are ignored. Other characters are copied straight to the application name. Note that it's not allowed to specify a plus/minus sign or a numeric literal after the `%` and before the option, for alignment and padding.

Escape	Effect
<code>%a</code>	Application name on local server
<code>%c</code>	Session ID on local server (see log_line_prefix for details)
<code>%C</code>	Cluster name on local server (see cluster_name for details)
<code>%u</code>	User name on local server
<code>%d</code>	Database name on local server
<code>%p</code>	Process ID of backend on local server
<code>%%</code>	Literal <code>%</code>

For example, suppose user `local_user` establishes a connection from database `local_db` to foreign_db as user `foreign_user`, the setting `'db=%d, user=%u'` is replaced with `'db=local_db, user=local_user'`.

F.57.9. Examples

Here is an example of creating a foreign table with `postgres_fdw`. First install the extension:

```
CREATE EXTENSION postgres_fdw;
```

Then create a foreign server using [CREATE SERVER](#). In this example we wish to connect to a Postgres Pro server on host `192.83.123.89` listening on port `5432`. The database to which the connection is made is named `foreign_db` on the remote server:

```
CREATE SERVER foreign_server
    FOREIGN DATA WRAPPER postgres_fdw
    OPTIONS (host '192.83.123.89', port '5432', dbname 'foreign_db');
```

A user mapping, defined with [CREATE USER MAPPING](#), is needed as well to identify the role that will be used on the remote server:

```
CREATE USER MAPPING FOR local_user
    SERVER foreign_server
    OPTIONS (user 'foreign_user', password 'password');
```

Now it is possible to create a foreign table with `CREATE FOREIGN TABLE`. In this example we wish to access the table named `some_schema.some_table` on the remote server. The local name for it will be `foreign_table`:

```
CREATE FOREIGN TABLE foreign_table (  
    id integer NOT NULL,  
    data text  
)  
  
    SERVER foreign_server  
    OPTIONS (schema_name 'some_schema', table_name 'some_table');
```

It's essential that the data types and other properties of the columns declared in `CREATE FOREIGN TABLE` match the actual remote table. Column names must match as well, unless you attach `column_name` options to the individual columns to show how they are named in the remote table. In many cases, use of `IMPORT FOREIGN SCHEMA` is preferable to constructing foreign table definitions manually.

F.57.10. Author

Shigeru Hanada <shigeru.hanada@gmail.com>

F.58. ptrack — a block-level incremental backup engine for Postgres Pro

PTRACK is a block-level incremental backup engine for Postgres Pro. If PTRACK is enabled, backup tools like [pg_probackup](#) can use its API to get information on the changed blocks on the fly when taking incremental backups. Copying only those blocks that have changed since the previous backup can significantly speed up the creation and minimize the size of backups.

PTRACK is designed to allow false positives, but to never allow false negatives: it means that all changes within the data directory except hint bits are guaranteed to be marked in the PTRACK map file, although some unchanged blocks might be included as well.

F.58.1. Setting up PTRACK

Once you complete Postgres Pro Standard installation, do the following:

1. Add `ptrack` to the [shared_preload_libraries](#) parameter in the `postgresql.conf` file:

```
shared_preload_libraries = 'ptrack'
```

2. Set [ptrack.map_size](#) parameter to a positive integer.

For optimal performance, it is recommended to set `ptrack.map_size` to $N / 1024$, where N is the size of the Postgres Pro cluster, in MB. If you set this parameter to a lower value, PTRACK is more likely to map several blocks together, which leads to false-positive results when tracking changed blocks and increases the incremental backup size as unchanged blocks can also be copied into the incremental backup.

Setting `ptrack.map_size` to a higher value does not affect PTRACK operation, but keep in mind that you need up to `ptrack.map_size * 3` MB of additional disk space since PTRACK uses two additional temporary files to ensure durability. It is not recommended to set this parameter to a value higher than 1024. Even for Postgres Pro clusters with $N > 1$ TB, it makes sense to use a higher value only if the efficiency and sizes of backups are more critical than the potential overhead of maintaining a large PTRACK map.

3. Check the [wal_level](#) setting. When using PTRACK, it is required to set the [wal_level](#) parameter to `replica` or higher. Otherwise, you can lose some tracked changes if crash-recovery occurs: some commands do not write WAL at all if `wal_level` is `minimal`, and PTRACK map files are flushed to disk only at checkpoint time.
4. Restart the Postgres Pro Standard instance for the changes to take effect, and then create the PTRACK extension:

```
CREATE EXTENSION ptrack;
```

As a result, several PTRACK functions are created, which are required for accessing PTRACK data.

Once this setup is complete, PTRACK starts tracking all the page changes in the Postgres Pro cluster and creates a `ptrack.map` file that stores the latest LSN values for these pages.

Note

The `ptrack.map_size` parameter can only be set at server start. If you change this parameter, the previously created PTRACK map file is cleared, and tracking newly changed blocks starts from scratch. To avoid losing recent changes, it is recommended to retake a full backup after modifying this setting.

F.58.2. PTRACK Configuration Parameters

`ptrack.map_size (integer)`

Specifies the size of a PTRACK map file and the amount of shared memory allocated for this file, in MB. The PTRACK map file stores the latest LSN values for all pages of the Postgres Pro cluster that have changed since PTRACK was enabled. It is not recommended to set this parameter to a value higher than 1GB. The 0 value disables PTRACK and cleans up all the related service files.

The `ptrack.map_size` parameter can only be set at server start. If you change this parameter, the previously created PTRACK map file is cleared, and tracking newly changed blocks starts from scratch. To avoid losing recent changes, it is recommended to retake a full backup after modifying this setting.

Default: 0

F.58.3. PTRACK Functions

`ptrack_init_lsn()` returns `pg_lsn`

Returns the LSN of the last PTRACK map initialization.

`ptrack_get_pagemapset (start_lsn pg_lsn)` returns `setof record`

Returns a list of data files changed since the specified `start_lsn` with the number and bitmap of changed pages for each file.

For example:

```
postgres=# SELECT * FROM ptrack_get_pagemapset ('0/185C8C0');
      path      | pagecount |          pagemap
-----+-----+-----
base/16384/1255 |          3 | \x00100000000050000000000000
base/16384/2674 |          3 | \x0000000900010000000000000000
base/16384/2691 |          1 | \x0000400000000000000000000000
base/16384/2608 |          1 | \x0000000000000000400000000000000000
base/16384/2690 |          1 | \x00040000000000000000000000
```

`ptrack_get_change_stat (start_lsn pg_lsn)` returns `record`

Returns the statistics of changes (number of files, number of changed pages and their total size in MB) since the specified `start_lsn`.

For example:

```
postgres=# SELECT * FROM ptrack_get_change_stat ('0/285C8C8');
 files | pages |      size, MB
-----+-----+-----
    20 |    25 | 0.19531250000000000000
```

`ptrack_version()` returns `text`

Returns PTRACK version.

F.59. rum — an access method to work with the RUM indexes

F.59.1. Introduction

The **rum** module provides access method to work with the RUM indexes. It is based on the GIN access method code.

GIN index allows you to perform fast full-text search using `tsvector` and `tsquery` types. However, full-text search with GIN index has some performance issues because positional and other additional information is not stored.

RUM solves these issues by storing additional information in a posting tree. As compared to GIN, RUM index has the following benefits:

- Faster ranking. Ranking requires positional information. And after the index scan we do not need an additional heap scan to retrieve lexeme positions because RUM index stores them.
- Faster phrase search. This improvement is related to the previous one as phrase search also needs positional information.
- Faster ordering by timestamp. RUM index stores additional information together with lexemes, so it is not necessary to perform a heap scan.
- A possibility to perform depth-first search and therefore return first results immediately.

The drawback of RUM is that it has slower build and insert time as compared to GIN because RUM stores additional information together with keys and uses generic WAL records.

F.59.2. Installation

`rum` is a Postgres Pro Standard extension and it has no special prerequisites.

Install extension as follows:

```
$ psql dbname -c "CREATE EXTENSION rum"
```

F.59.3. Common Operators

The operators provided by the `rum` module are shown in [Table F.36](#):

Table F.36. `rum` Operators

Operator	Returns	Description
<code>tsvector <=> tsquery</code>	<code>float4</code>	Returns distance between <code>tsvector</code> and <code>tsquery</code> values.
<code>timestamp <=> timestamp</code>	<code>float8</code>	Returns distance between two <code>timestamp</code> values.
<code>timestamp <= timestamp</code>	<code>float8</code>	Returns distance only for ascending <code>timestamp</code> values.
<code>timestamp => timestamp</code>	<code>float8</code>	Returns distance only for descending <code>timestamp</code> values.

Note

`rum` introduces its own ranking function that is executed inside the `<=>` operator. It calculates the score (inverted distance) using the specified normalization method. This function is a combination of `ts_rank` and `ts_rank_cd` (see [Section 9.13](#) for details). While `ts_rank` does not support logical

operators and `ts_rank_cd` works poorly with OR queries, the `rum`-specific ranking function overcomes these drawbacks.

F.59.4. Operator Classes

The `rum` extension provides the following operator classes:

`rum_tsvector_ops`

Stores `tsvector` lexemes with positional information. Supports ordering by `<=>` operator and prefix search.

`rum_tsvector_hash_ops`

Stores hash of `tsvector` lexemes with positional information. Supports ordering by `<=>` operator, but does not support prefix search.

`rum_tsvector_addon_ops`

Stores `tsvector` lexemes with additional data of any type supported by `RUM`.

Note

To use the `rum_tsvector_addon_ops` operator class, when creating the `RUM` index with `CREATE INDEX`, specify the `attach` and `to` storage parameters in the `WITH` clause.

`rum_tsvector_hash_addon_ops`

Stores `tsvector` lexemes with additional data of any type supported by `RUM`. Does not support prefix search.

`rum_tsquery_ops`

Stores branches of query tree in additional information.

`rum_anyarray_ops`

Stores `anyarray` elements with length of the array. Supports ordering by `<=>` operator.

Indexable operators: `&&` `@>` `<@` `=` `%`

`rum_anyarray_addon_ops`

Stores `anyarray` elements with additional data of any type supported by `RUM`.

`rum_type_ops`

Stores lexemes of the corresponding type with positional information. The `type` placeholder in the class name must be substituted by one of the following type names: `int2`, `int4`, `int8`, `float4`, `float8`, `money`, `oid`, `timestamp`, `timestampz`, `time`, `timetz`, `date`, `interval`, `macaddr`, `inet`, `cidr`, `text`, `varchar`, `char`, `bytea`, `bit`, `varbit`, `numeric`.

`rum_type_ops` supports ordering by `<=>`, `<=|`, and `|=>` operators. This operator class can be used together with `rum_tsvector_addon_ops`, `rum_tsvector_hash_addon_ops`, and `rum_anyarray_addon_ops` operator classes.

Supported indexable operators depend on the data type:

- `<` `<=` `=` `>=` `>` `<=>` `<=|` `|=>` are supported for `int2`, `int4`, `int8`, `float4`, `float8`, `money`, `oid`, `timestamp`, `timestampz`.

- `< <= = >= >` are supported for time, timetz, date, interval, macaddr, inet, cidr, text, varchar, char, bytea, bit, varbit, numeric.

Note

The following operator classes are now deprecated: `rum_tsvector_timestamp_ops`, `rum_tsvector_timestamptz_ops`, `rum_tsvector_hash_timestamp_ops`, `rum_tsvector_hash_timestamptz_ops`.

F.59.5. Examples

F.59.5.1. rum_tsvector_ops Example

Let's assume we have the following table:

```
CREATE TABLE test_rum(t text, a tsvector);

CREATE TRIGGER tsvectorupdate
BEFORE UPDATE OR INSERT ON test_rum
FOR EACH ROW EXECUTE PROCEDURE tsvector_update_trigger('a', 'pg_catalog.english', 't');

INSERT INTO test_rum(t) VALUES ('The situation is most beautiful');
INSERT INTO test_rum(t) VALUES ('It is a beautiful');
INSERT INTO test_rum(t) VALUES ('It looks like a beautiful place');
```

Then we can create a new index:

```
CREATE INDEX rumidx ON test_rum USING rum (a rum_tsvector_ops);
```

And we can execute the following queries:

```
SELECT t, a <=> to_tsquery('english', 'beautiful | place') AS rank
FROM test_rum
WHERE a @@ to_tsquery('english', 'beautiful | place')
ORDER BY a <=> to_tsquery('english', 'beautiful | place');
      t              | rank
-----+-----
The situation is most beautiful | 0.0303964
It is a beautiful              | 0.0303964
It looks like a beautiful place | 0.0607927
(3 rows)
```

```
SELECT t, a <=> to_tsquery('english', 'place | situation') AS rank
FROM test_rum
WHERE a @@ to_tsquery('english', 'place | situation')
ORDER BY a <=> to_tsquery('english', 'place | situation');
      t              | rank
-----+-----
The situation is most beautiful | 0.0303964
It looks like a beautiful place | 0.0303964
(2 rows)
```

F.59.5.2. rum_tsvector_addon_ops Example

Let's assume we have the following table:

```
CREATE TABLE tsts (id int, t tsvector, d timestamp);

\copy tsts from 'rum/data/tsts.data'
```

```
CREATE INDEX tst_idx ON tst USING rum (t rum_tsvector_addon_ops, d)
WITH (attach = 'd', to = 't');
```

Now we can execute the following queries:

```
EXPLAIN (costs off)
  SELECT id, d, d <=> '2016-05-16 14:21:25' FROM tst WHERE t @@ 'wr&qh' ORDER BY d
  <=> '2016-05-16 14:21:25' LIMIT 5;
                                QUERY PLAN
```

```
-----
Limit
->  Index Scan using tst_idx on tst
      Index Cond: (t @@ ''wr'' & ''qh''::tsquery)
      Order By: (d <=> 'Mon May 16 14:21:25 2016'::timestamp without time zone)
(4 rows)
```

```
SELECT id, d, d <=> '2016-05-16 14:21:25' FROM tst WHERE t @@ 'wr&qh' ORDER BY d <=>
'2016-05-16 14:21:25' LIMIT 5;
```

id	d	?column?
355	Mon May 16 14:21:22.326724 2016	2.673276
354	Mon May 16 13:21:22.326724 2016	3602.673276
371	Tue May 17 06:21:22.326724 2016	57597.326724
406	Wed May 18 17:21:22.326724 2016	183597.326724
415	Thu May 19 02:21:22.326724 2016	215997.326724

(5 rows)

F.59.5.3. rum_tsquery_ops Example

Suppose we have the table:

```
CREATE TABLE query (q tsquery, tag text);

INSERT INTO query VALUES ('supernova & star', 'sn'),
  ('black', 'color'),
  ('big & bang & black & hole', 'bang'),
  ('spiral & galaxy', 'shape'),
  ('black & hole', 'color');
```

```
CREATE INDEX query_idx ON query USING rum(q);
```

We can execute the following fast query:

```
SELECT * FROM query
  WHERE to_tsvector('black holes never exists before we think about them') @@ q;
      q      | tag
-----+-----
'black'      | color
'black' & 'hole' | color
(2 rows)
```

F.59.5.4. rum_anyarray_ops Example

Let's assume we have the following table:

```
CREATE TABLE test_array (i int2[]);

INSERT INTO test_array VALUES ('{}'), ('{0}'), ('{1,2,3,4}'), ('{1,2,3}'), ('{1,2}'),
  ('{1}');

CREATE INDEX idx_array ON test_array USING rum (i rum_anyarray_ops);
```

Now we can execute the following query using index scan:

```
SET enable_seqscan TO off;

EXPLAIN (COSTS OFF) SELECT * FROM test_array WHERE i && '{1}' ORDER BY i <=> '{1}' ASC;
      QUERY PLAN
-----
Index Scan using idx_array on test_array
  Index Cond: (i && '{1}'::smallint[])
  Order By: (i <=> '{1}'::smallint[])
(3 rows)

SELECT * FROM test_array WHERE i && '{1}' ORDER BY i <=> '{1}' ASC;
      i
-----
 {1}
 {1,2}
 {1,2,3}
 {1,2,3,4}
(4 rows)
```

F.60. seg — a datatype for line segments or floating point intervals

This module implements a data type `seg` for representing line segments, or floating point intervals. `seg` can represent uncertainty in the interval endpoints, making it especially useful for representing laboratory measurements.

This module is considered “trusted”, that is, it can be installed by non-superusers who have `CREATE` privilege on the current database.

F.60.1. Rationale

The geometry of measurements is usually more complex than that of a point in a numeric continuum. A measurement is usually a segment of that continuum with somewhat fuzzy limits. The measurements come out as intervals because of uncertainty and randomness, as well as because the value being measured may naturally be an interval indicating some condition, such as the temperature range of stability of a protein.

Using just common sense, it appears more convenient to store such data as intervals, rather than pairs of numbers. In practice, it even turns out more efficient in most applications.

Further along the line of common sense, the fuzziness of the limits suggests that the use of traditional numeric data types leads to a certain loss of information. Consider this: your instrument reads 6.50, and you input this reading into the database. What do you get when you fetch it? Watch:

```
test=> select 6.50 :: float8 as "pH";
      pH
-----
6.5
(1 row)
```

In the world of measurements, 6.50 is not the same as 6.5. It may sometimes be critically different. The experimenters usually write down (and publish) the digits they trust. 6.50 is actually a fuzzy interval contained within a bigger and even fuzzier interval, 6.5, with their center points being (probably) the only common feature they share. We definitely do not want such different data items to appear the same.

Conclusion? It is nice to have a special data type that can record the limits of an interval with arbitrarily variable precision. Variable in the sense that each data element records its own precision.

Check this out:

```
test=> select '6.25 .. 6.50'::seg as "pH";
      pH
-----
6.25 .. 6.50
(1 row)
```

F.60.2. Syntax

The external representation of an interval is formed using one or two floating-point numbers joined by the range operator (`..` or `...`). Alternatively, it can be specified as a center point plus or minus a deviation. Optional certainty indicators (`<`, `>` or `~`) can be stored as well. (Certainty indicators are ignored by all the built-in operators, however.) [Table F.37](#) gives an overview of allowed representations; [Table F.38](#) shows some examples.

In [Table F.37](#), *x*, *y*, and *delta* denote floating-point numbers. *x* and *y*, but not *delta*, can be preceded by a certainty indicator.

Table F.37. `seg` External Representations

<i>x</i>	Single value (zero-length interval)

$x \dots y$	Interval from x to y
$x \ (+-) \ \textit{delta}$	Interval from $x - \textit{delta}$ to $x + \textit{delta}$
$x \dots$	Open interval with lower bound x
$\dots x$	Open interval with upper bound x

Table F.38. Examples of Valid `seg` Input

5.0	Creates a zero-length segment (a point, if you will)
~5.0	Creates a zero-length segment and records ~ in the data. ~ is ignored by <code>seg</code> operations, but is preserved as a comment.
<5.0	Creates a point at 5.0. < is ignored but is preserved as a comment.
>5.0	Creates a point at 5.0. > is ignored but is preserved as a comment.
5 (+-) 0.3	Creates an interval 4.7 .. 5.3. Note that the (+-) notation isn't preserved.
50 ..	Everything that is greater than or equal to 50
.. 0	Everything that is less than or equal to 0
1.5e-2 .. 2E-2	Creates an interval 0.015 .. 0.02
1 ... 2	The same as 1...2, or 1 .. 2, or 1..2 (spaces around the range operator are ignored)

Because the ... operator is widely used in data sources, it is allowed as an alternative spelling of the .. operator. Unfortunately, this creates a parsing ambiguity: it is not clear whether the upper bound in 0...23 is meant to be 23 or 0.23. This is resolved by requiring at least one digit before the decimal point in all numbers in `seg` input.

As a sanity check, `seg` rejects intervals with the lower bound greater than the upper, for example 5 .. 2.

F.60.3. Precision

`seg` values are stored internally as pairs of 32-bit floating point numbers. This means that numbers with more than 7 significant digits will be truncated.

Numbers with 7 or fewer significant digits retain their original precision. That is, if your query returns 0.00, you will be sure that the trailing zeroes are not the artifacts of formatting: they reflect the precision of the original data. The number of leading zeroes does not affect precision: the value 0.0067 is considered to have just 2 significant digits.

F.60.4. Usage

The `seg` module includes a GiST index operator class for `seg` values. The operators supported by the GiST operator class are shown in [Table F.39](#).

Table F.39. Seg GiST Operators

Operator	Description
<code>seg << seg → boolean</code>	Is the first <code>seg</code> entirely to the left of the second? $[a, b] << [c, d]$ is true if $b < c$.
<code>seg >> seg → boolean</code>	Is the first <code>seg</code> entirely to the right of the second? $[a, b] >> [c, d]$ is true if $a > d$.
<code>seg &< seg → boolean</code>	Does the first <code>seg</code> not extend to the right of the second? $[a, b] \&< [c, d]$ is true if $b \leq d$.

Operator	Description
<code>seg &> seg → boolean</code>	Does the first <code>seg</code> not extend to the left of the second? <code>[a, b] &> [c, d]</code> is true if <code>a >= c</code> .
<code>seg = seg → boolean</code>	Are the two <code>segs</code> equal?
<code>seg && seg → boolean</code>	Do the two <code>segs</code> overlap?
<code>seg @> seg → boolean</code>	Does the first <code>seg</code> contain the second?
<code>seg <@ seg → boolean</code>	Is the first <code>seg</code> contained in the second?

In addition to the above operators, the usual comparison operators shown in [Table 9.1](#) are available for type `seg`. These operators first compare (a) to (c), and if these are equal, compare (b) to (d). That results in reasonably good sorting in most cases, which is useful if you want to use ORDER BY with this type.

F.60.5. Notes

For examples of usage, see the regression test `sql/seg.sql`.

The mechanism that converts `(+-)` to regular ranges isn't completely accurate in determining the number of significant digits for the boundaries. For example, it adds an extra digit to the lower boundary if the resulting interval includes a power of ten:

```
postgres=> select '10(+-)1'::seg as seg;
      seg
-----
9.0 .. 11          -- should be: 9 .. 11
```

The performance of an R-tree index can largely depend on the initial order of input values. It may be very helpful to sort the input table on the `seg` column; see the script `sort-segments.pl` for an example.

F.60.6. Credits

Original author: Gene Selkov, Jr. <selkovjr@mcs.anl.gov>, Mathematics and Computer Science Division, Argonne National Laboratory.

My thanks are primarily to Prof. Joe Hellerstein (<https://dsf.berkeley.edu/jmh/>) for elucidating the gist of the GiST (<http://gist.cs.berkeley.edu/>). I am also grateful to all Postgres developers, present and past, for enabling myself to create my own world and live undisturbed in it. And I would like to acknowledge my gratitude to Argonne Lab and to the U.S. Department of Energy for the years of faithful support of my database research.

F.61. sepysql — SELinux-, label-based mandatory access control (MAC) security module

`sepysql` is a loadable module that supports label-based mandatory access control (MAC) based on SELinux security policy.

Warning

The current implementation has significant limitations, and does not enforce mandatory access control for all actions. See [Section F.61.7](#).

F.61.1. Overview

This module integrates with SELinux to provide an additional layer of security checking above and beyond what is normally provided by Postgres Pro. From the perspective of SELinux, this module allows Postgres Pro to function as a user-space object manager. Each table or function access initiated by a DML query will be checked against the system security policy. This check is in addition to the usual SQL permissions checking performed by Postgres Pro.

SELinux access control decisions are made using security labels, which are represented by strings such as `system_u:object_r:sepysql_table_t:s0`. Each access control decision involves two labels: the label of the subject attempting to perform the action, and the label of the object on which the operation is to be performed. Since these labels can be applied to any sort of object, access control decisions for objects stored within the database can be (and, with this module, are) subjected to the same general criteria used for objects of any other type, such as files. This design is intended to allow a centralized security policy to protect information assets independent of the particulars of how those assets are stored.

The `SECURITY LABEL` statement allows assignment of a security label to a database object.

F.61.2. Installation

`sepysql` can only be used on Linux 2.6.28 or higher with SELinux enabled. It is not available on any other platform. You will also need `libselinux` 2.1.10 or higher and `selinux-policy` 3.9.13 or higher (although some distributions may backport the necessary rules into older policy versions).

The `sestatus` command allows you to check the status of SELinux. A typical display is:

```
$ sestatus
SELinux status:                enabled
SELinuxfs mount:              /selinux
Current mode:                  enforcing
Mode from config file:         enforcing
Policy version:                24
Policy from config file:       targeted
```

If SELinux is disabled or not installed, you must set that product up first before installing this module.

To build this module, include the option `--with-selinux` in your Postgres Pro `configure` command. Be sure that the `libselinux-devel` RPM is installed at build time.

To use this module, you must include `sepysql` in the `shared_preload_libraries` parameter in `postgresql.conf`. The module will not function correctly if loaded in any other manner. Once the module is loaded, you should execute `sepysql.sql` in each database. This will install functions needed for security label management, and assign initial security labels.

Here is an example showing how to initialize a fresh database cluster with `sepysql` functions and security labels installed. Adjust the paths shown as appropriate for your installation:

```
$ export PGDATA=/path/to/data/directory
$ initdb
```

Additional Supplied Modules and Extensions Shipped in postgrespro-std-16-contrib

```
$ vi $PGDATA/postgresql.conf
change
    #shared_preload_libraries = ''          # (change requires restart)
to
    shared_preload_libraries = 'sepgsql'    # (change requires restart)
$ for DBNAME in template0 template1 postgres; do
    postgres --single -F -c exit_on_error=true $DBNAME \
        </usr/local/pgsql/share/contrib/sepgsql.sql >/dev/null
done
```

Please note that you may see some or all of the following notifications depending on the particular versions you have of `libselinux` and `selinux-policy`:

```
/etc/selinux/targeted/contexts/sepgsql_contexts: line 33 has invalid object type
db_blobs
/etc/selinux/targeted/contexts/sepgsql_contexts: line 36 has invalid object type
db_language
/etc/selinux/targeted/contexts/sepgsql_contexts: line 37 has invalid object type
db_language
/etc/selinux/targeted/contexts/sepgsql_contexts: line 38 has invalid object type
db_language
/etc/selinux/targeted/contexts/sepgsql_contexts: line 39 has invalid object type
db_language
/etc/selinux/targeted/contexts/sepgsql_contexts: line 40 has invalid object type
db_language
```

These messages are harmless and should be ignored.

If the installation process completes without error, you can now start the server normally.

F.61.3. Regression Tests

Due to the nature of SELinux, running the regression tests for `sepgsql` requires several extra configuration steps, some of which must be done as root. The regression tests will not be run by an ordinary `make check` or `make installcheck` command; you must set up the configuration and then invoke the test script manually. The tests must be run in the `contrib/sepgsql` directory of a configured Postgres Pro build tree. Although they require a build tree, the tests are designed to be executed against an installed server, that is they are comparable to `make installcheck` not `make check`.

First, set up `sepgsql` in a working database according to the instructions in [Section F.61.2](#). Note that the current operating system user must be able to connect to the database as superuser without password authentication.

Second, build and install the policy package for the regression test. The `sepgsql-regtest` policy is a special purpose policy package which provides a set of rules to be allowed during the regression tests. It should be built from the policy source file `sepgsql-regtest.te`, which is done using `make` with a Makefile supplied by SELinux. You will need to locate the appropriate Makefile on your system; the path shown below is only an example. (This Makefile is usually supplied by the `selinux-policy-devel` or `selinux-policy` RPM.) Once built, install this policy package using the `semodule` command, which loads supplied policy packages into the kernel. If the package is correctly installed, `semodule -l` should list `sepgsql-regtest` as an available policy package:

```
$ cd .../contrib/sepgsql
$ make -f /usr/share/selinux/devel/Makefile
$ sudo semodule -u sepgsql-regtest.pp
$ sudo semodule -l | grep sepgsql
sepgsql-regtest 1.07
```

Third, turn on `sepgsql_regression_test_mode`. For security reasons, the rules in `sepgsql-regtest` are not enabled by default; the `sepgsql_regression_test_mode` parameter enables the rules needed to launch the regression tests. It can be turned on using the `setsebool` command:

```
$ sudo setsebool sepysql_regression_test_mode on
$ getsebool sepysql_regression_test_mode
sepysql_regression_test_mode --> on
```

Fourth, verify your shell is operating in the `unconfined_t` domain:

```
$ id -Z
unconfined_u:unconfined_r:unconfined_t:s0-s0:c0.c1023
```

See [Section F.61.8](#) for details on adjusting your working domain, if necessary.

Finally, run the regression test script:

```
$ ./test_sepysql
```

This script will attempt to verify that you have done all the configuration steps correctly, and then it will run the regression tests for the `sepysql` module.

After completing the tests, it's recommended you disable the `sepysql_regression_test_mode` parameter:

```
$ sudo setsebool sepysql_regression_test_mode off
```

You might prefer to remove the `sepysql-regtest` policy entirely:

```
$ sudo semodule -r sepysql-regtest
```

F.61.4. GUC Parameters

`sepysql.permissive` (boolean)

This parameter enables `sepysql` to function in permissive mode, regardless of the system setting. The default is off. This parameter can only be set in the `postgresql.conf` file or on the server command line.

When this parameter is on, `sepysql` functions in permissive mode, even if SELinux in general is working in enforcing mode. This parameter is primarily useful for testing purposes.

`sepysql.debug_audit` (boolean)

This parameter enables the printing of audit messages regardless of the system policy settings. The default is off, which means that messages will be printed according to the system settings.

The security policy of SELinux also has rules to control whether or not particular accesses are logged. By default, access violations are logged, but allowed accesses are not.

This parameter forces all possible logging to be turned on, regardless of the system policy.

F.61.5. Features

F.61.5.1. Controlled Object Classes

The security model of SELinux describes all the access control rules as relationships between a subject entity (typically, a client of the database) and an object entity (such as a database object), each of which is identified by a security label. If access to an unlabeled object is attempted, the object is treated as if it were assigned the label `unlabeled_t`.

Currently, `sepysql` allows security labels to be assigned to schemas, tables, columns, sequences, views, and functions. When `sepysql` is in use, security labels are automatically assigned to supported database objects at creation time. This label is called a default security label, and is decided according to the system security policy, which takes as input the creator's label, the label assigned to the new object's parent object and optionally name of the constructed object.

A new database object basically inherits the security label of the parent object, except when the security policy has special rules known as type-transition rules, in which case a different label may be applied.

For schemas, the parent object is the current database; for tables, sequences, views, and functions, it is the containing schema; for columns, it is the containing table.

F.61.5.2. DML Permissions

For tables, `db_table:select`, `db_table:insert`, `db_table:update` or `db_table:delete` are checked for all the referenced target tables depending on the kind of statement; in addition, `db_table:select` is also checked for all the tables that contain columns referenced in the `WHERE` or `RETURNING` clause, as a data source for `UPDATE`, and so on.

Column-level permissions will also be checked for each referenced column. `db_column:select` is checked on not only the columns being read using `SELECT`, but those being referenced in other DML statements; `db_column:update` or `db_column:insert` will also be checked for columns being modified by `UPDATE` or `INSERT`.

For example, consider:

```
UPDATE t1 SET x = 2, y = func1(y) WHERE z = 100;
```

Here, `db_column:update` will be checked for `t1.x`, since it is being updated, `db_column:{select update}` will be checked for `t1.y`, since it is both updated and referenced, and `db_column:select` will be checked for `t1.z`, since it is only referenced. `db_table:{select update}` will also be checked at the table level.

For sequences, `db_sequence:get_value` is checked when we reference a sequence object using `SELECT`; however, note that we do not currently check permissions on execution of corresponding functions such as `lastval()`.

For views, `db_view:expand` will be checked, then any other required permissions will be checked on the objects being expanded from the view, individually.

For functions, `db_procedure:{execute}` will be checked when user tries to execute a function as a part of query, or using fast-path invocation. If this function is a trusted procedure, it also checks `db_procedure:{entrypoint}` permission to check whether it can perform as entry point of trusted procedure.

In order to access any schema object, `db_schema:search` permission is required on the containing schema. When an object is referenced without schema qualification, schemas on which this permission is not present will not be searched (just as if the user did not have `USAGE` privilege on the schema). If an explicit schema qualification is present, an error will occur if the user does not have the requisite permission on the named schema.

The client must be allowed to access all referenced tables and columns, even if they originated from views which were then expanded, so that we apply consistent access control rules independent of the manner in which the table contents are referenced.

The default database privilege system allows database superusers to modify system catalogs using DML commands, and reference or modify toast tables. These operations are prohibited when `sepgsql` is enabled.

F.61.5.3. DDL Permissions

SELinux defines several permissions to control common operations for each object type; such as creation, alter, drop and relabel of security label. In addition, several object types have special permissions to control their characteristic operations; such as addition or deletion of name entries within a particular schema.

Creating a new database object requires `create` permission. SELinux will grant or deny this permission based on the client's security label and the proposed security label for the new object. In some cases, additional privileges are required:

- `CREATE DATABASE` additionally requires `getattr` permission for the source or template database.
- Creating a schema object additionally requires `add_name` permission on the parent schema.

- Creating a table additionally requires permission to create each individual table column, just as if each table column were a separate top-level object.
- Creating a function marked as `LEAKPROOF` additionally requires `install` permission. (This permission is also checked when `LEAKPROOF` is set for an existing function.)

When `DROP` command is executed, `drop` will be checked on the object being removed. Permissions will be also checked for objects dropped indirectly via `CASCADE`. Deletion of objects contained within a particular schema (tables, views, sequences and procedures) additionally requires `remove_name` on the schema.

When `ALTER` command is executed, `setattr` will be checked on the object being modified for each object types, except for subsidiary objects such as the indexes or triggers of a table, where permissions are instead checked on the parent object. In some cases, additional permissions are required:

- Moving an object to a new schema additionally requires `remove_name` permission on the old schema and `add_name` permission on the new one.
- Setting the `LEAKPROOF` attribute on a function requires `install` permission.
- Using `SECURITY LABEL` on an object additionally requires `relabelfrom` permission for the object in conjunction with its old security label and `relabelto` permission for the object in conjunction with its new security label. (In cases where multiple label providers are installed and the user tries to set a security label, but it is not managed by SELinux, only `setattr` should be checked here. This is currently not done due to implementation restrictions.)

F.61.5.4. Trusted Procedures

Trusted procedures are similar to security definer functions or `setuid` commands. SELinux provides a feature to allow trusted code to run using a security label different from that of the client, generally for the purpose of providing highly controlled access to sensitive data (e.g., rows might be omitted, or the precision of stored values might be reduced). Whether or not a function acts as a trusted procedure is controlled by its security label and the operating system security policy. For example:

```
postgres=# CREATE TABLE customer (  
            cid      int primary key,  
            cname    text,  
            credit    text  
        );  
CREATE TABLE  
postgres=# SECURITY LABEL ON COLUMN customer.credit  
            IS 'system_u:object_r:sepgsql_secret_table_t:s0';  
SECURITY LABEL  
postgres=# CREATE FUNCTION show_credit(int) RETURNS text  
            AS 'SELECT regexp_replace(credit, '[0-9]+$',' -xxxx', 'g')  
                FROM customer WHERE cid = $1'  
            LANGUAGE sql;  
CREATE FUNCTION  
postgres=# SECURITY LABEL ON FUNCTION show_credit(int)  
            IS 'system_u:object_r:sepgsql_trusted_proc_exec_t:s0';  
SECURITY LABEL
```

The above operations should be performed by an administrative user.

```
postgres=# SELECT * FROM customer;  
ERROR:  SELinux: security policy violation  
postgres=# SELECT cid, cname, show_credit(cid) FROM customer;  
cid | cname | show_credit  
----+-----+-----  
  1 | taro  | 1111-2222-3333-xxxx  
  2 | hanako | 5555-6666-7777-xxxx  
(2 rows)
```

In this case, a regular user cannot reference `customer.credit` directly, but a trusted procedure `show_credit` allows the user to print the credit card numbers of customers with some of the digits masked out.

F.61.5.5. Dynamic Domain Transitions

It is possible to use SELinux's dynamic domain transition feature to switch the security label of the client process, the client domain, to a new context, if that is allowed by the security policy. The client domain needs the `setcurrent` permission and also `dyntransition` from the old to the new domain.

Dynamic domain transitions should be considered carefully, because they allow users to switch their label, and therefore their privileges, at their option, rather than (as in the case of a trusted procedure) as mandated by the system. Thus, the `dyntransition` permission is only considered safe when used to switch to a domain with a smaller set of privileges than the original one. For example:

```
regression=# select sepgsql_getcon();
              sepgsql_getcon
-----
unconfined_u:unconfined_r:unconfined_t:s0-s0:c0.c1023
(1 row)

regression=# SELECT sepgsql_setcon('unconfined_u:unconfined_r:unconfined_t:s0-
s0:c1.c4');
      sepgsql_setcon
-----
t
(1 row)

regression=# SELECT sepgsql_setcon('unconfined_u:unconfined_r:unconfined_t:s0-
s0:c1.c1023');
ERROR:  SELinux: security policy violation
```

In this example above we were allowed to switch from the larger MCS range `c1.c1023` to the smaller range `c1.c4`, but switching back was denied.

A combination of dynamic domain transition and trusted procedure enables an interesting use case that fits the typical process life-cycle of connection pooling software. Even if your connection pooling software is not allowed to run most of SQL commands, you can allow it to switch the security label of the client using the `sepgsql_setcon()` function from within a trusted procedure; that should take some credential to authorize the request to switch the client label. After that, this session will have the privileges of the target user, rather than the connection pooler. The connection pooler can later revert the security label change by again using `sepgsql_setcon()` with `NULL` argument, again invoked from within a trusted procedure with appropriate permissions checks. The point here is that only the trusted procedure actually has permission to change the effective security label, and only does so when given proper credentials. Of course, for secure operation, the credential store (table, procedure definition, or whatever) must be protected from unauthorized access.

F.61.5.6. Miscellaneous

We reject the `LOAD` command across the board, because any module loaded could easily circumvent security policy enforcement.

F.61.6. Sepgsql Functions

Table F.40 shows the available functions.

Table F.40. Sepgsql Functions

Function	Description
<code>sepgsql_getcon ()</code>	<code>→ text</code>

Function	Description
	Returns the client domain, the current security label of the client.
<code>sepgsql_setcon (text) → boolean</code>	Switches the client domain of the current session to the new domain, if allowed by the security policy. It also accepts <code>NULL</code> input as a request to transition to the client's original domain.
<code>sepgsql_mcstrans_in (text) → text</code>	Translates the given qualified MLS/MCS range into raw format if the mcstrans daemon is running.
<code>sepgsql_mcstrans_out (text) → text</code>	Translates the given raw MLS/MCS range into qualified format if the mcstrans daemon is running.
<code>sepgsql_restorecon (text) → boolean</code>	Sets up initial security labels for all objects within the current database. The argument may be <code>NULL</code> , or the name of a specfile to be used as alternative of the system default.

F.61.7. Limitations

Data Definition Language (DDL) Permissions

Due to implementation restrictions, some DDL operations do not check permissions.

Data Control Language (DCL) Permissions

Due to implementation restrictions, DCL operations do not check permissions.

Row-level access control

Postgres Pro supports row-level access, but `sepgsql` does not.

Covert channels

`sepgsql` does not try to hide the existence of a certain object, even if the user is not allowed to reference it. For example, we can infer the existence of an invisible object as a result of primary key conflicts, foreign key violations, and so on, even if we cannot obtain the contents of the object. The existence of a top secret table cannot be hidden; we only hope to conceal its contents.

F.62. shared_ispell — a shared ispell dictionary

The `shared_ispell` module provides a shared ispell dictionary, i.e. a dictionary that's stored in shared segment. The traditional ispell implementation means that each session initializes and stores the dictionary on it's own, which means a lot of CPU/RAM is wasted.

This extension allocates an area in shared segment (you have to choose the size in advance) and then loads the dictionary into it when it's used for the first time.

F.62.1. Functions

The functions provided by the `shared_ispell` module are shown in [Table F.41](#).

Table F.41. `shared_ispell` Functions

Function	Returns	Description
<code>shared_ispell_reset()</code>	void	Resets the dictionaries (e.g. so that you can reload the updated files from disk). The sessions that already use the dictionaries will be forced to reinitialize them.
<code>shared_ispell_mem_used()</code>	int	Returns a value of used memory of the shared segment by loaded shared dictionaries in bytes.
<code>shared_ispell_mem_available()</code>	int	Returns a value of available memory of the shared segment.
<code>shared_ispell_dicts()</code>	<code>setof(dict_name varchar, affix_name varchar, words int, affixes int, bytes int)</code>	Returns a list of dictionaries loaded in the shared segment.
<code>shared_ispell_stoplists()</code>	<code>setof(stop_name varchar, words int, bytes int)</code>	Returns a list of stopwords loaded in the shared segment.

F.62.2. GUC Parameters

`shared_ispell.max_size (int)`

Defines the maximum size of the shared segment. This is a hard limit, the shared segment is not extensible and you need to set it so that all the dictionaries fit into it and not much memory is wasted.

F.62.3. Using the dictionary

The module needs to allocate space in the shared memory segment. So add this to the config file (or update the current values):

```
# libraries to load
shared_preload_libraries = 'shared_ispell'

# config of the shared memory
shared_ispell.max_size = 32MB
```

To find out how much memory you actually need, use a large value (e.g. 200MB) and load all the dictionaries you want to use. Then use the `shared_ispell_mem_used()` function to find out how much memory was actually used (and set the `shared_ispell.max_size` GUC variable accordingly).

Don't set it exactly to that value, leave there some free space, so that you can reload the dictionaries without changing the GUC `max_size` limit (which requires a restart of the DB). Something like 512kB should be just fine.

The extension defines a `shared_ispell` template that you may use to define custom dictionaries. E.g. you may do this:

```
CREATE TEXT SEARCH DICTIONARY english_shared (
    TEMPLATE = shared_ispell,
    DictFile = en_us,
    AffFile = en_us,
    StopWords = english
);

CREATE TEXT SEARCH CONFIGURATION public.english_shared
    ( COPY = pg_catalog.simple );

ALTER TEXT SEARCH CONFIGURATION english_shared
    ALTER MAPPING FOR asciiword, asciihword, hword_asciipart,
        word, hword, hword_part
    WITH english_shared, english_stem;
```

We can test created configuration:

```
SELECT * FROM ts_debug('english_shared', 'abilities');
      alias | description | token | dictionaries | dictionary
      | lexemes
-----+-----+-----+-----+-----
+-----+-----+-----+-----+-----
  asciiword | Word, all ASCII | abilities | {english_shared,english_stem} |
  english_shared | {ability}
(1 row)
```

Or you can update your own text search configuration. For example, you have the `public.english` dictionary. You can update it to use the `shared_ispell` template:

```
ALTER TEXT SEARCH CONFIGURATION public.english
    ALTER MAPPING FOR asciiword, asciihword, hword_asciipart,
        word, hword, hword_part
    WITH english_shared, english_stem;
```

F.63. spi — Server Programming Interface features/examples

The spi module provides several workable examples of using the [Server Programming Interface](#) (SPI) and triggers. While these functions are of some value in their own right, they are even more useful as examples to modify for your own purposes. The functions are general enough to be used with any table, but you have to specify table and field names (as described below) while creating a trigger.

Each of the groups of functions described below is provided as a separately-installable extension.

F.63.1. refint — Functions for Implementing Referential Integrity

`check_primary_key()` and `check_foreign_key()` are used to check foreign key constraints. (This functionality is long since superseded by the built-in foreign key mechanism, of course, but the module is still useful as an example.)

`check_primary_key()` checks the referencing table. To use, create a `BEFORE INSERT OR UPDATE` trigger using this function on a table referencing another table. Specify as the trigger arguments: the referencing table's column name(s) which form the foreign key, the referenced table name, and the column names in the referenced table which form the primary/unique key. To handle multiple foreign keys, create a trigger for each reference.

`check_foreign_key()` checks the referenced table. To use, create a `BEFORE DELETE OR UPDATE` trigger using this function on a table referenced by other table(s). Specify as the trigger arguments: the number of referencing tables for which the function has to perform checking, the action if a referencing key is found (`cascade` — to delete the referencing row, `restrict` — to abort transaction if referencing keys exist, `setnull` — to set referencing key fields to null), the triggered table's column names which form the primary/unique key, then the referencing table name and column names (repeated for as many referencing tables as were specified by first argument). Note that the primary/unique key columns should be marked `NOT NULL` and should have a unique index.

There are examples in `refint.example`.

F.63.2. autoinc — Functions for Autoincrementing Fields

`autoinc()` is a trigger that stores the next value of a sequence into an integer field. This has some overlap with the built-in “serial column” feature, but it is not the same: `autoinc()` will override attempts to substitute a different field value during inserts, and optionally it can be used to increment the field during updates, too.

To use, create a `BEFORE INSERT` (or optionally `BEFORE INSERT OR UPDATE`) trigger using this function. Specify two trigger arguments: the name of the integer column to be modified, and the name of the sequence object that will supply values. (Actually, you can specify any number of pairs of such names, if you'd like to update more than one autoincrementing column.)

There is an example in `autoinc.example`.

F.63.3. insert_username — Functions for Tracking Who Changed a Table

`insert_username()` is a trigger that stores the current user's name into a text field. This can be useful for tracking who last modified a particular row within a table.

To use, create a `BEFORE INSERT` and/or `UPDATE` trigger using this function. Specify a single trigger argument: the name of the text column to be modified.

There is an example in `insert_username.example`.

F.63.4. moddatetime — Functions for Tracking Last Modification Time

`moddatetime()` is a trigger that stores the current time into a `timestamp` field. This can be useful for tracking the last modification time of a particular row within a table.

To use, create a `BEFORE UPDATE` trigger using this function. Specify a single trigger argument: the name of the column to be modified. The column must be of type `timestamp` or `timestamp with time zone`.

There is an example in `moddatetime.example`.

F.64. sslinfo — obtain client SSL information

The `sslinfo` module provides information about the SSL certificate that the current client provided when connecting to Postgres Pro. The module is useless (most functions will return NULL) if the current connection does not use SSL.

Some of the information available through this module can also be obtained using the built-in system view `pg_stat_ssl`.

This extension won't build at all unless the installation was configured with `--with-ssl=openssl`.

F.64.1. Functions Provided

`ssl_is_used()` returns boolean

Returns true if current connection to server uses SSL, and false otherwise.

`ssl_version()` returns text

Returns the name of the protocol used for the SSL connection (e.g., TLSv1.0, TLSv1.1, TLSv1.2 or TLSv1.3).

`ssl_cipher()` returns text

Returns the name of the cipher used for the SSL connection (e.g., DHE-RSA-AES256-SHA).

`ssl_client_cert_present()` returns boolean

Returns true if current client has presented a valid SSL client certificate to the server, and false otherwise. (The server might or might not be configured to require a client certificate.)

`ssl_client_serial()` returns numeric

Returns serial number of current client certificate. The combination of certificate serial number and certificate issuer is guaranteed to uniquely identify a certificate (but not its owner — the owner ought to regularly change their keys, and get new certificates from the issuer).

So, if you run your own CA and allow only certificates from this CA to be accepted by the server, the serial number is the most reliable (albeit not very mnemonic) means to identify a user.

`ssl_client_dn()` returns text

Returns the full subject of the current client certificate, converting character data into the current database encoding. It is assumed that if you use non-ASCII characters in the certificate names, your database is able to represent these characters, too. If your database uses the SQL_ASCII encoding, non-ASCII characters in the name will be represented as UTF-8 sequences.

The result looks like `/CN=Somebody /C=Some country/O=Some organization`.

`ssl_issuer_dn()` returns text

Returns the full issuer name of the current client certificate, converting character data into the current database encoding. Encoding conversions are handled the same as for `ssl_client_dn`.

The combination of the return value of this function with the certificate serial number uniquely identifies the certificate.

This function is really useful only if you have more than one trusted CA certificate in your server's certificate authority file, or if this CA has issued some intermediate certificate authority certificates.

`ssl_client_dn_field(fieldname text)` returns text

This function returns the value of the specified field in the certificate subject, or NULL if the field is not present. Field names are string constants that are converted into ASN1 object identifiers using the OpenSSL object database. The following values are acceptable:

commonName (alias CN)
surname (alias SN)
name
givenName (alias GN)
countryName (alias C)
localityName (alias L)
stateOrProvinceName (alias ST)
organizationName (alias O)
organizationalUnitName (alias OU)
title
description
initials
postalCode
streetAddress
generationQualifier
description
dnQualifier
x500UniqueIdentifier
pseudonym
role
emailAddress

All of these fields are optional, except `commonName`. It depends entirely on your CA's policy which of them would be included and which wouldn't. The meaning of these fields, however, is strictly defined by the X.500 and X.509 standards, so you cannot just assign arbitrary meaning to them.

`ssl_issuer_field(fieldname text)` returns text

Same as `ssl_client_dn_field`, but for the certificate issuer rather than the certificate subject.

`ssl_extension_info()` returns setof record

Provide information about extensions of client certificate: extension name, extension value, and if it is a critical extension.

F.65. tablefunc — functions that return tables (crosstab and others)

The `tablefunc` module includes various functions that return tables (that is, multiple rows). These functions are useful both in their own right and as examples of how to write C functions that return multiple rows.

This module is considered “trusted”, that is, it can be installed by non-superusers who have `CREATE` privilege on the current database.

F.65.1. Functions Provided

Table F.42 summarizes the functions provided by the `tablefunc` module.

Table F.42. tablefunc Functions

Function	Description
<code>normal_rand (numvals integer, mean float8, stddev float8) → setof float8</code>	Produces a set of normally distributed random values.
<code>crosstab (sql text) → setof record</code>	Produces a “pivot table” containing row names plus <i>N</i> value columns, where <i>N</i> is determined by the row type specified in the calling query.
<code>crosstabN (sql text) → setof table_crosstab_ N</code>	Produces a “pivot table” containing row names plus <i>N</i> value columns. <code>crosstab2</code> , <code>crosstab3</code> , and <code>crosstab4</code> are predefined, but you can create additional <code>crosstabN</code> functions as described below.
<code>crosstab (source_sql text, category_sql text) → setof record</code>	Produces a “pivot table” with the value columns specified by a second query.
<code>crosstab (sql text, N integer) → setof record</code>	Obsolete version of <code>crosstab(text)</code> . The parameter <i>N</i> is now ignored, since the number of value columns is always determined by the calling query.
<code>connectby (relname text, keyid_fld text, parent_keyid_fld text [, orderby_fld text], start_with text, max_depth integer [, branch_delim text]) → setof record</code>	Produces a representation of a hierarchical tree structure.

F.65.1.1. normal_rand

`normal_rand(int numvals, float8 mean, float8 stddev)` returns `setof float8`

`normal_rand` produces a set of normally distributed random values (Gaussian distribution).

numvals is the number of values to be returned from the function. *mean* is the mean of the normal distribution of values and *stddev* is the standard deviation of the normal distribution of values.

For example, this call requests 1000 values with a mean of 5 and a standard deviation of 3:

```
test=# SELECT * FROM normal_rand(1000, 5, 3);
normal_rand
-----
 1.56556322244898
 9.10040991424657
 5.36957140345079
-0.369151492880995
 0.283600703686639
```

```
.  
. .  
4.82992125404908  
9.71308014517282  
2.49639286969028  
(1000 rows)
```

F.65.1.2. crosstab(text)

```
crosstab(text sql)  
crosstab(text sql, int N)
```

The `crosstab` function is used to produce “pivot” displays, wherein data is listed across the page rather than down. For example, we might have data like

```
row1    val11  
row1    val12  
row1    val13  
...  
row2    val21  
row2    val22  
row2    val23  
...
```

which we wish to display like

```
row1    val11    val12    val13    ...  
row2    val21    val22    val23    ...  
...
```

The `crosstab` function takes a text parameter that is an SQL query producing raw data formatted in the first way, and produces a table formatted in the second way.

The `sql` parameter is an SQL statement that produces the source set of data. This statement must return one `row_name` column, one `category` column, and one `value` column. `N` is an obsolete parameter, ignored if supplied (formerly this had to match the number of output value columns, but now that is determined by the calling query).

For example, the provided query might produce a set something like:

row_name	cat	value
row1	cat1	val1
row1	cat2	val2
row1	cat3	val3
row1	cat4	val4
row2	cat1	val5
row2	cat2	val6
row2	cat3	val7
row2	cat4	val8

The `crosstab` function is declared to return `setof record`, so the actual names and types of the output columns must be defined in the `FROM` clause of the calling `SELECT` statement, for example:

```
SELECT * FROM crosstab('...') AS ct(row_name text, category_1 text, category_2 text);
```

This example produces a set something like:

	<== value columns ==>	
row_name	category_1	category_2
row1	val1	val2

row2	val5	val6

The `FROM` clause must define the output as one `row_name` column (of the same data type as the first result column of the SQL query) followed by `N value` columns (all of the same data type as the third result column of the SQL query). You can set up as many output value columns as you wish. The names of the output columns are up to you.

The `crosstab` function produces one output row for each consecutive group of input rows with the same `row_name` value. It fills the output value columns, left to right, with the value fields from these rows. If there are fewer rows in a group than there are output value columns, the extra output columns are filled with nulls; if there are more rows, the extra input rows are skipped.

In practice the SQL query should always specify `ORDER BY 1, 2` to ensure that the input rows are properly ordered, that is, values with the same `row_name` are brought together and correctly ordered within the row. Notice that `crosstab` itself does not pay any attention to the second column of the query result; it's just there to be ordered by, to control the order in which the third-column values appear across the page.

Here is a complete example:

```
CREATE TABLE ct(id SERIAL, rowid TEXT, attribute TEXT, value TEXT);
INSERT INTO ct(rowid, attribute, value) VALUES('test1','att1','val1');
INSERT INTO ct(rowid, attribute, value) VALUES('test1','att2','val2');
INSERT INTO ct(rowid, attribute, value) VALUES('test1','att3','val3');
INSERT INTO ct(rowid, attribute, value) VALUES('test1','att4','val4');
INSERT INTO ct(rowid, attribute, value) VALUES('test2','att1','val5');
INSERT INTO ct(rowid, attribute, value) VALUES('test2','att2','val6');
INSERT INTO ct(rowid, attribute, value) VALUES('test2','att3','val7');
INSERT INTO ct(rowid, attribute, value) VALUES('test2','att4','val8');
```

```
SELECT *
FROM crosstab(
    'select rowid, attribute, value
    from ct
    where attribute = ''att2'' or attribute = ''att3''
    order by 1,2')
AS ct(row_name text, category_1 text, category_2 text, category_3 text);
```

row_name	category_1	category_2	category_3
test1	val2	val3	
test2	val6	val7	

(2 rows)

You can avoid always having to write out a `FROM` clause to define the output columns, by setting up a custom `crosstab` function that has the desired output row type wired into its definition. This is described in the next section. Another possibility is to embed the required `FROM` clause in a view definition.

Note

See also the `\crosstabview` command in `psql`, which provides functionality similar to `crosstab()`.

F.65.1.3. `crosstabN(text)`

`crosstabN(text sql)`

The `crosstabN` functions are examples of how to set up custom wrappers for the general `crosstab` function, so that you need not write out column names and types in the calling `SELECT` query. The `tablefunc` module includes `crosstab2`, `crosstab3`, and `crosstab4`, whose output row types are defined as

```
CREATE TYPE tablefunc_crosstab_N AS (  
    row_name TEXT,  
    category_1 TEXT,  
    category_2 TEXT,  
    .  
    .  
    .  
    category_N TEXT  
);
```

Thus, these functions can be used directly when the input query produces `row_name` and `value` columns of type `text`, and you want 2, 3, or 4 output values columns. In all other ways they behave exactly as described above for the general `crosstab` function.

For instance, the example given in the previous section would also work as

```
SELECT *  
FROM crosstab3(  
    'select rowid, attribute, value  
    from ct  
    where attribute = ''att2'' or attribute = ''att3''  
    order by 1,2');
```

These functions are provided mostly for illustration purposes. You can create your own return types and functions based on the underlying `crosstab()` function. There are two ways to do it:

- Create a composite type describing the desired output columns, similar to the examples in `contrib/tablefunc/tablefunc--1.0.sql`. Then define a unique function name accepting one `text` parameter and returning `setof your_type_name`, but linking to the same underlying `crosstab C` function. For example, if your source data produces row names that are `text`, and values that are `float8`, and you want 5 value columns:

```
CREATE TYPE my_crosstab_float8_5_cols AS (  
    my_row_name text,  
    my_category_1 float8,  
    my_category_2 float8,  
    my_category_3 float8,  
    my_category_4 float8,  
    my_category_5 float8  
);  
  
CREATE OR REPLACE FUNCTION crosstab_float8_5_cols(text)  
    RETURNS setof my_crosstab_float8_5_cols  
    AS '$libdir/tablefunc', 'crosstab' LANGUAGE C STABLE STRICT;
```

- Use `OUT` parameters to define the return type implicitly. The same example could also be done this way:

```
CREATE OR REPLACE FUNCTION crosstab_float8_5_cols(  
    IN text,  
    OUT my_row_name text,  
    OUT my_category_1 float8,  
    OUT my_category_2 float8,  
    OUT my_category_3 float8,  
    OUT my_category_4 float8,  
    OUT my_category_5 float8)  
    RETURNS setof record  
    AS '$libdir/tablefunc', 'crosstab' LANGUAGE C STABLE STRICT;
```

F.65.1.4. `crosstab(text, text)`

```
crosstab(text source_sql, text category_sql)
```

The main limitation of the single-parameter form of `crosstab` is that it treats all values in a group alike, inserting each value into the first available column. If you want the value columns to correspond to specific categories of data, and some groups might not have data for some of the categories, that doesn't work well. The two-parameter form of `crosstab` handles this case by providing an explicit list of the categories corresponding to the output columns.

`source_sql` is an SQL statement that produces the source set of data. This statement must return one `row_name` column, one `category` column, and one `value` column. It may also have one or more “extra” columns. The `row_name` column must be first. The `category` and `value` columns must be the last two columns, in that order. Any columns between `row_name` and `category` are treated as “extra”. The “extra” columns are expected to be the same for all rows with the same `row_name` value.

For example, `source_sql` might produce a set something like:

```
SELECT row_name, extra_col, cat, value FROM foo ORDER BY 1;
```

row_name	extra_col	cat	value
row1	extra1	cat1	val1
row1	extra1	cat2	val2
row1	extra1	cat4	val4
row2	extra2	cat1	val5
row2	extra2	cat2	val6
row2	extra2	cat3	val7
row2	extra2	cat4	val8

`category_sql` is an SQL statement that produces the set of categories. This statement must return only one column. It must produce at least one row, or an error will be generated. Also, it must not produce duplicate values, or an error will be generated. `category_sql` might be something like:

```
SELECT DISTINCT cat FROM foo ORDER BY 1;
cat
-----
cat1
cat2
cat3
cat4
```

The `crosstab` function is declared to return `setof record`, so the actual names and types of the output columns must be defined in the `FROM` clause of the calling `SELECT` statement, for example:

```
SELECT * FROM crosstab('...', '...')
AS ct(row_name text, extra text, cat1 text, cat2 text, cat3 text, cat4 text);
```

This will produce a result something like:

		<== value columns ==>			
row_name	extra	cat1	cat2	cat3	cat4
row1	extra1	val1	val2		val4
row2	extra2	val5	val6	val7	val8

The `FROM` clause must define the proper number of output columns of the proper data types. If there are N columns in the `source_sql` query's result, the first $N-2$ of them must match up with the first $N-2$ output columns. The remaining output columns must have the type of the last column of the `source_sql` query's result, and there must be exactly as many of them as there are rows in the `category_sql` query's result.

The `crosstab` function produces one output row for each consecutive group of input rows with the same `row_name` value. The output `row_name` column, plus any “extra” columns, are copied from the first row of the group. The output `value` columns are filled with the `value` fields from rows having matching

category values. If a row's category does not match any output of the *category_sql* query, its value is ignored. Output columns whose matching category is not present in any input row of the group are filled with nulls.

In practice the *source_sql* query should always specify `ORDER BY 1` to ensure that values with the same *row_name* are brought together. However, ordering of the categories within a group is not important. Also, it is essential to be sure that the order of the *category_sql* query's output matches the specified output column order.

Here are two complete examples:

```
create table sales(year int, month int, qty int);
insert into sales values(2007, 1, 1000);
insert into sales values(2007, 2, 1500);
insert into sales values(2007, 7, 500);
insert into sales values(2007, 11, 1500);
insert into sales values(2007, 12, 2000);
insert into sales values(2008, 1, 1000);
```

```
select * from crosstab(
    'select year, month, qty from sales order by 1',
    'select m from generate_series(1,12) m'
) as (
    year int,
    "Jan" int,
    "Feb" int,
    "Mar" int,
    "Apr" int,
    "May" int,
    "Jun" int,
    "Jul" int,
    "Aug" int,
    "Sep" int,
    "Oct" int,
    "Nov" int,
    "Dec" int
);
 year | Jan  | Feb  | Mar  | Apr  | May  | Jun  | Jul  | Aug  | Sep  | Oct  | Nov  | Dec
-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----
 2007 | 1000 | 1500 |      |      |      |      | 500  |      |      |      | 1500 | 2000
 2008 | 1000 |      |      |      |      |      |      |      |      |      |      |
(2 rows)
```

```
CREATE TABLE cth(rowid text, rowdt timestamp, attribute text, val text);
INSERT INTO cth VALUES('test1','01 March 2003','temperature','42');
INSERT INTO cth VALUES('test1','01 March 2003','test_result','PASS');
INSERT INTO cth VALUES('test1','01 March 2003','volts','2.6987');
INSERT INTO cth VALUES('test2','02 March 2003','temperature','53');
INSERT INTO cth VALUES('test2','02 March 2003','test_result','FAIL');
INSERT INTO cth VALUES('test2','02 March 2003','test_startdate','01 March 2003');
INSERT INTO cth VALUES('test2','02 March 2003','volts','3.1234');

SELECT * FROM crosstab
(
    'SELECT rowid, rowdt, attribute, val FROM cth ORDER BY 1',
    'SELECT DISTINCT attribute FROM cth ORDER BY 1'
)
AS
(
```

```

rowid text,
rowdt timestamp,
temperature int4,
test_result text,
test_startdate timestamp,
volts float8
);
rowid |          rowdt          | temperature | test_result |          test_startdate
| volts
-----+-----+-----+-----+-----
test1 | Sat Mar 01 00:00:00 2003 |          42 | PASS        |
| 2.6987
test2 | Sun Mar 02 00:00:00 2003 |          53 | FAIL        | Sat Mar 01 00:00:00
2003 | 3.1234
(2 rows)

```

You can create predefined functions to avoid having to write out the result column names and types in each query. See the examples in the previous section. The underlying C function for this form of `crosstab` is named `crosstab_hash`.

F.65.1.5. `connectby`

```

connectby(text relname, text keyid_fld, text parent_keyid_fld
[, text orderby_fld ], text start_with, int max_depth
[, text branch_delim ])

```

The `connectby` function produces a display of hierarchical data that is stored in a table. The table must have a key field that uniquely identifies rows, and a parent-key field that references the parent (if any) of each row. `connectby` can display the sub-tree descending from any row.

Table F.43 explains the parameters.

Table F.43. `connectby` Parameters

Parameter	Description
<i>relname</i>	Name of the source relation
<i>keyid_fld</i>	Name of the key field
<i>parent_keyid_fld</i>	Name of the parent-key field
<i>orderby_fld</i>	Name of the field to order siblings by (optional)
<i>start_with</i>	Key value of the row to start at
<i>max_depth</i>	Maximum depth to descend to, or zero for unlimited depth
<i>branch_delim</i>	String to separate keys with in branch output (optional)

The key and parent-key fields can be any data type, but they must be the same type. Note that the *start_with* value must be entered as a text string, regardless of the type of the key field.

The `connectby` function is declared to return `setof record`, so the actual names and types of the output columns must be defined in the `FROM` clause of the calling `SELECT` statement, for example:

```

SELECT * FROM connectby('connectby_tree', 'keyid', 'parent_keyid', 'pos', 'row2', 0,
 '~')
AS t(keyid text, parent_keyid text, level int, branch text, pos int);

```

The first two output columns are used for the current row's key and its parent row's key; they must match the type of the table's key field. The third output column is the depth in the tree and must be

of type `integer`. If a `branch_delim` parameter was given, the next output column is the branch display and must be of type `text`. Finally, if an `orderby_fld` parameter was given, the last output column is a serial number, and must be of type `integer`.

The “branch” output column shows the path of keys taken to reach the current row. The keys are separated by the specified `branch_delim` string. If no branch display is wanted, omit both the `branch_delim` parameter and the branch column in the output column list.

If the ordering of siblings of the same parent is important, include the `orderby_fld` parameter to specify which field to order siblings by. This field can be of any sortable data type. The output column list must include a final integer serial-number column, if and only if `orderby_fld` is specified.

The parameters representing table and field names are copied as-is into the SQL queries that `connectby` generates internally. Therefore, include double quotes if the names are mixed-case or contain special characters. You may also need to schema-qualify the table name.

In large tables, performance will be poor unless there is an index on the parent-key field.

It is important that the `branch_delim` string not appear in any key values, else `connectby` may incorrectly report an infinite-recursion error. Note that if `branch_delim` is not provided, a default value of `~` is used for recursion detection purposes.

Here is an example:

```
CREATE TABLE connectby_tree(keyid text, parent_keyid text, pos int);
```

```
INSERT INTO connectby_tree VALUES('row1',NULL, 0);
INSERT INTO connectby_tree VALUES('row2','row1', 0);
INSERT INTO connectby_tree VALUES('row3','row1', 0);
INSERT INTO connectby_tree VALUES('row4','row2', 1);
INSERT INTO connectby_tree VALUES('row5','row2', 0);
INSERT INTO connectby_tree VALUES('row6','row4', 0);
INSERT INTO connectby_tree VALUES('row7','row3', 0);
INSERT INTO connectby_tree VALUES('row8','row6', 0);
INSERT INTO connectby_tree VALUES('row9','row5', 0);
```

```
-- with branch, without orderby_fld (order of results is not guaranteed)
SELECT * FROM connectby('connectby_tree', 'keyid', 'parent_keyid', 'row2', 0, '~')
AS t(keyid text, parent_keyid text, level int, branch text);
keyid | parent_keyid | level |      branch
```

keyid	parent_keyid	level	branch
row2		0	row2
row4	row2	1	row2~row4
row6	row4	2	row2~row4~row6
row8	row6	3	row2~row4~row6~row8
row5	row2	1	row2~row5
row9	row5	2	row2~row5~row9

(6 rows)

```
-- without branch, without orderby_fld (order of results is not guaranteed)
SELECT * FROM connectby('connectby_tree', 'keyid', 'parent_keyid', 'row2', 0)
AS t(keyid text, parent_keyid text, level int);
keyid | parent_keyid | level
```

keyid	parent_keyid	level
row2		0
row4	row2	1
row6	row4	2
row8	row6	3
row5	row2	1

Additional Supplied Modules
and Extensions Shipped in
postgrespro-std-16-contrib

```
row9 | row5 | 2
(6 rows)
```

```
-- with branch, with orderby_fld (notice that row5 comes before row4)
SELECT * FROM connectby('connectby_tree', 'keyid', 'parent_keyid', 'pos', 'row2', 0,
 '~')
AS t(keyid text, parent_keyid text, level int, branch text, pos int);
keyid | parent_keyid | level |      branch      | pos

(6 rows)
```

F.65.2. Author

Joe Conway

F.66. tcn — a trigger function to notify listeners of changes to table content

The `tcn` module provides a trigger function that notifies listeners of changes to any table on which it is attached. It must be used as an `AFTER` trigger `FOR EACH ROW`.

This module is considered “trusted”, that is, it can be installed by non-superusers who have `CREATE` privilege on the current database.

Only one parameter may be supplied to the function in a `CREATE TRIGGER` statement, and that is optional. If supplied it will be used for the channel name for the notifications. If omitted `tcn` will be used for the channel name.

The payload of the notifications consists of the table name, a letter to indicate which type of operation was performed, and column name/value pairs for primary key columns. Each part is separated from the next by a comma. For ease of parsing using regular expressions, table and column names are always wrapped in double quotes, and data values are always wrapped in single quotes. Embedded quotes are doubled.

A brief example of using the extension follows.

```
test=# create table tcndata
test=# (
test(#   a int not null,
test(#   b date not null,
test(#   c text,
test(#   primary key (a, b)
test(# );
CREATE TABLE
test=# create trigger tcndata_tcn_trigger
test=#   after insert or update or delete on tcndata
test=#   for each row execute function triggered_change_notification();
CREATE TRIGGER
test=# listen tcn;
LISTEN
test=# insert into tcndata values (1, date '2012-12-22', 'one'),
test=#                                     (1, date '2012-12-23', 'another'),
test=#                                     (2, date '2012-12-23', 'two');
INSERT 0 3
Asynchronous notification "tcn" with payload ""tcndata",I,"a"='1',"b"='2012-12-22'"
received from server process with PID 22770.
Asynchronous notification "tcn" with payload ""tcndata",I,"a"='1',"b"='2012-12-23'"
received from server process with PID 22770.
Asynchronous notification "tcn" with payload ""tcndata",I,"a"='2',"b"='2012-12-23'"
received from server process with PID 22770.
test=# update tcndata set c = 'uno' where a = 1;
UPDATE 2
Asynchronous notification "tcn" with payload ""tcndata",U,"a"='1',"b"='2012-12-22'"
received from server process with PID 22770.
Asynchronous notification "tcn" with payload ""tcndata",U,"a"='1',"b"='2012-12-23'"
received from server process with PID 22770.
test=# delete from tcndata where a = 1 and b = date '2012-12-22';
DELETE 1
Asynchronous notification "tcn" with payload ""tcndata",D,"a"='1',"b"='2012-12-22'"
received from server process with PID 22770.
```

F.67. test_decoding — SQL-based test/example module for WAL logical decoding

`test_decoding` is an example of a logical decoding output plugin. It doesn't do anything especially useful, but can serve as a starting point for developing your own output plugin.

`test_decoding` receives WAL through the logical decoding mechanism and decodes it into text representations of the operations performed.

Typical output from this plugin, used over the SQL logical decoding interface, might be:

```
postgres=# SELECT * FROM pg_logical_slot_get_changes('test_slot', NULL, NULL, 'include-
xids', '0');
 lsn      | xid | data
-----+-----+-----
 0/16D30F8 | 691 | BEGIN
 0/16D32A0 | 691 | table public.data: INSERT: id[int4]:2 data[text]:'arg'
 0/16D32A0 | 691 | table public.data: INSERT: id[int4]:3 data[text]:'demo'
 0/16D32A0 | 691 | COMMIT
 0/16D32D8 | 692 | BEGIN
 0/16D3398 | 692 | table public.data: DELETE: id[int4]:2
 0/16D3398 | 692 | table public.data: DELETE: id[int4]:3
 0/16D3398 | 692 | COMMIT
(8 rows)
```

We can also get the changes of the in-progress transaction, and the typical output might be:

```
postgres[33712]=#* SELECT * FROM pg_logical_slot_get_changes('test_slot', NULL, NULL,
'stream-changes', '1');
 lsn      | xid | data
-----+-----+-----
 0/16B21F8 | 503 | opening a streamed block for transaction TXN 503
 0/16B21F8 | 503 | streaming change for TXN 503
 0/16B2300 | 503 | streaming change for TXN 503
 0/16B2408 | 503 | streaming change for TXN 503
 0/16BEBA0 | 503 | closing a streamed block for transaction TXN 503
 0/16B21F8 | 503 | opening a streamed block for transaction TXN 503
 0/16BECA8 | 503 | streaming change for TXN 503
 0/16BEDB0 | 503 | streaming change for TXN 503
 0/16BEEB8 | 503 | streaming change for TXN 503
 0/16BEBA0 | 503 | closing a streamed block for transaction TXN 503
(10 rows)
```

F.68. `tsm_system_rows` — the `SYSTEM_ROWS` sampling method for `TABLESAMPLE`

The `tsm_system_rows` module provides the table sampling method `SYSTEM_ROWS`, which can be used in the `TABLESAMPLE` clause of a `SELECT` command.

This table sampling method accepts a single integer argument that is the maximum number of rows to read. The resulting sample will always contain exactly that many rows, unless the table does not contain enough rows, in which case the whole table is selected.

Like the built-in `SYSTEM` sampling method, `SYSTEM_ROWS` performs block-level sampling, so that the sample is not completely random but may be subject to clustering effects, especially if only a small number of rows are requested.

`SYSTEM_ROWS` does not support the `REPEATABLE` clause.

This module is considered “trusted”, that is, it can be installed by non-superusers who have `CREATE` privilege on the current database.

F.68.1. Examples

Here is an example of selecting a sample of a table with `SYSTEM_ROWS`. First install the extension:

```
CREATE EXTENSION tsm_system_rows;
```

Then you can use it in a `SELECT` command, for instance:

```
SELECT * FROM my_table TABLESAMPLE SYSTEM_ROWS(100);
```

This command will return a sample of 100 rows from the table `my_table` (unless the table does not have 100 visible rows, in which case all its rows are returned).

F.69. `tsm_system_time` — the `SYSTEM_TIME` sampling method for `TABLESAMPLE`

The `tsm_system_time` module provides the table sampling method `SYSTEM_TIME`, which can be used in the `TABLESAMPLE` clause of a `SELECT` command.

This table sampling method accepts a single floating-point argument that is the maximum number of milliseconds to spend reading the table. This gives you direct control over how long the query takes, at the price that the size of the sample becomes hard to predict. The resulting sample will contain as many rows as could be read in the specified time, unless the whole table has been read first.

Like the built-in `SYSTEM` sampling method, `SYSTEM_TIME` performs block-level sampling, so that the sample is not completely random but may be subject to clustering effects, especially if only a small number of rows are selected.

`SYSTEM_TIME` does not support the `REPEATABLE` clause.

This module is considered “trusted”, that is, it can be installed by non-superusers who have `CREATE` privilege on the current database.

F.69.1. Examples

Here is an example of selecting a sample of a table with `SYSTEM_TIME`. First install the extension:

```
CREATE EXTENSION tsm_system_time;
```

Then you can use it in a `SELECT` command, for instance:

```
SELECT * FROM my_table TABLESAMPLE SYSTEM_TIME(1000);
```

This command will return as large a sample of `my_table` as it can read in 1 second (1000 milliseconds). Of course, if the whole table can be read in under 1 second, all its rows will be returned.

F.70. unaccent — a text search dictionary which removes diacritics

`unaccent` is a text search dictionary that removes accents (diacritic signs) from lexemes. It's a filtering dictionary, which means its output is always passed to the next dictionary (if any), unlike the normal behavior of dictionaries. This allows accent-insensitive processing for full text search.

The current implementation of `unaccent` cannot be used as a normalizing dictionary for the `thesaurus` dictionary.

This module is considered “trusted”, that is, it can be installed by non-superusers who have `CREATE` privilege on the current database.

F.70.1. Configuration

An `unaccent` dictionary accepts the following options:

- `RULES` is the base name of the file containing the list of translation rules. This file must be stored in `$$SHAREDIR/tsearch_data/` (where `$$SHAREDIR` means the Postgres Pro installation's shared-data directory). Its name must end in `.rules` (which is not to be included in the `RULES` parameter).

The rules file has the following format:

- Each line represents one translation rule, consisting of a character with accent followed by a character without accent. The first is translated into the second. For example,

À	A
Á	A
Â	A
Ã	A
Ä	A
Å	A
Æ	AE

The two characters must be separated by whitespace, and any leading or trailing whitespace on a line is ignored.

- Alternatively, if only one character is given on a line, instances of that character are deleted; this is useful in languages where accents are represented by separate characters.
- Actually, each “character” can be any string not containing whitespace, so `unaccent` dictionaries could be used for other sorts of substring substitutions besides diacritic removal.
- As with other Postgres Pro text search configuration files, the rules file must be stored in UTF-8 encoding. The data is automatically translated into the current database's encoding when loaded. Any lines containing untranslatable characters are silently ignored, so that rules files can contain rules that are not applicable in the current encoding.

A more complete example, which is directly useful for most European languages, can be found in `unaccent.rules`, which is installed in `$$SHAREDIR/tsearch_data/` when the `unaccent` module is installed. This rules file translates characters with accents to the same characters without accents, and it also expands ligatures into the equivalent series of simple characters (for example, `Æ` to `AE`).

F.70.2. Usage

Installing the `unaccent` extension creates a text search template `unaccent` and a dictionary `unaccent` based on it. The `unaccent` dictionary has the default parameter setting `RULES='unaccent'`, which makes it immediately usable with the standard `unaccent.rules` file. If you wish, you can alter the parameter, for example

```
mydb=# ALTER TEXT SEARCH DICTIONARY unaccent (RULES='my_rules');
```

or create new dictionaries based on the template.

To test the dictionary, you can try:

```
mydb=# select ts_lexize('unaccent','Hôtel');
 ts_lexize
-----
 {Hotel}
(1 row)
```

Here is an example showing how to insert the `unaccent` dictionary into a text search configuration:

```
mydb=# CREATE TEXT SEARCH CONFIGURATION fr ( COPY = french );
mydb=# ALTER TEXT SEARCH CONFIGURATION fr
        ALTER MAPPING FOR hword, hword_part, word
        WITH unaccent, french_stem;
mydb=# select to_tsvector('fr','Hôtels de la Mer');
 to_tsvector
-----
 'hotel':1 'mer':4
(1 row)

mydb=# select to_tsvector('fr','Hôtel de la Mer') @@ to_tsquery('fr','Hotels');
 ?column?
-----
 t
(1 row)

mydb=# select ts_headline('fr','Hôtel de la Mer',to_tsquery('fr','Hotels'));
 ts_headline
-----
 <b>Hôtel</b> de la Mer
(1 row)
```

F.70.3. Functions

The `unaccent()` function removes accents (diacritic signs) from a given string. Basically, it's a wrapper around `unaccent`-type dictionaries, but it can be used outside normal text search contexts.

`unaccent([dictionary regdictionary, ] string text)` returns text

If the *dictionary* argument is omitted, the text search dictionary named `unaccent` and appearing in the same schema as the `unaccent()` function itself is used.

For example:

```
SELECT unaccent('unaccent', 'Hôtel');
SELECT unaccent('Hôtel');
```

F.71. uuid-ossdp — a UUID generator

The `uuid-ossdp` module provides functions to generate universally unique identifiers (UUIDs) using one of several standard algorithms. There are also functions to produce certain special UUID constants. This module is only necessary for special requirements beyond what is available in core Postgres Pro. See [Section 9.14](#) for built-in ways to generate UUIDs.

This module is considered “trusted”, that is, it can be installed by non-superusers who have `CREATE` privilege on the current database.

F.71.1. uuid-ossdp Functions

[Table F.44](#) shows the functions available to generate UUIDs. The relevant standards ITU-T Rec. X.667, ISO/IEC 9834-8:2005, and [RFC 4122](#) specify four algorithms for generating UUIDs, identified by the version numbers 1, 3, 4, and 5. (There is no version 2 algorithm.) Each of these algorithms could be suitable for a different set of applications.

Table F.44. Functions for UUID Generation

Function	Description
<code>uuid_generate_v1 () → uuid</code>	Generates a version 1 UUID. This involves the MAC address of the computer and a time stamp. Note that UUIDs of this kind reveal the identity of the computer that created the identifier and the time at which it did so, which might make it unsuitable for certain security-sensitive applications.
<code>uuid_generate_v1mc () → uuid</code>	Generates a version 1 UUID, but uses a random multicast MAC address instead of the real MAC address of the computer.
<code>uuid_generate_v3 (namespace uuid, name text) → uuid</code>	Generates a version 3 UUID in the given namespace using the specified input name. The namespace should be one of the special constants produced by the <code>uuid_ns_*</code> () functions shown in Table F.45 . (It could be any UUID in theory.) The name is an identifier in the selected namespace. For example: <pre>SELECT uuid_generate_v3(uuid_ns_url(), 'http://www.postgresql.org');</pre> The name parameter will be MD5-hashed, so the cleartext cannot be derived from the generated UUID. The generation of UUIDs by this method has no random or environment-dependent element and is therefore reproducible.
<code>uuid_generate_v4 () → uuid</code>	Generates a version 4 UUID, which is derived entirely from random numbers.
<code>uuid_generate_v5 (namespace uuid, name text) → uuid</code>	Generates a version 5 UUID, which works like a version 3 UUID except that SHA-1 is used as a hashing method. Version 5 should be preferred over version 3 because SHA-1 is thought to be more secure than MD5.

Table F.45. Functions Returning UUID Constants

Function	Description
<code>uuid_nil () → uuid</code>	Returns a “nil” UUID constant, which does not occur as a real UUID.
<code>uuid_ns_dns () → uuid</code>	Returns a constant designating the DNS namespace for UUIDs.

Function	Description
<code>uuid_ns_url</code> <code>() → uuid</code>	Returns a constant designating the URL namespace for UUIDs.
<code>uuid_ns_oid</code> <code>() → uuid</code>	Returns a constant designating the ISO object identifier (OID) namespace for UUIDs. (This pertains to ASN.1 OIDs, which are unrelated to the OIDs used in Postgres Pro.)
<code>uuid_ns_x500</code> <code>() → uuid</code>	Returns a constant designating the X.500 distinguished name (DN) namespace for UUIDs.

F.71.2. Building `uuid-oss`

Historically this module depended on the OSSP UUID library, which accounts for the module's name. While the OSSP UUID library can still be found at <http://www.ossdp.org/pkg/lib/uuid/>, it is not well maintained, and is becoming increasingly difficult to port to newer platforms. `uuid-oss` can now be built without the OSSP library on some platforms. On FreeBSD and some other BSD-derived platforms, suitable UUID creation functions are included in the core `libc` library. On Linux, macOS, and some other platforms, suitable functions are provided in the `libuuid` library, which originally came from the `e2fsprogs` project (though on modern Linux it is considered part of `util-linux-ng`). When invoking `configure`, specify `--with-uuid=bsd` to use the BSD functions, or `--with-uuid=e2fs` to use `e2fsprogs`' `libuuid`, or `--with-uuid=oss` to use the OSSP UUID library. More than one of these libraries might be available on a particular machine, so `configure` does not automatically choose one.

F.71.3. Author

Peter Eisentraut <peter_e@gmx.net>

F.72. xml2 — XPath querying and XSLT functionality

The `xml2` module provides XPath querying and XSLT functionality.

F.72.1. Deprecation Notice

From PostgreSQL 8.3 on, there is XML-related functionality based on the SQL/XML standard in the core server. That functionality covers XML syntax checking and XPath queries, which is what this module does, and more, but the API is not at all compatible. It is planned that this module will be removed in a future version of Postgres Pro in favor of the newer standard API, so you are encouraged to try converting your applications. If you find that some of the functionality of this module is not available in an adequate form with the newer API, please explain your issue to pgsql-hackers@lists.postgresql.org so that the deficiency can be addressed.

F.72.2. Description of Functions

[Table F.46](#) shows the functions provided by this module. These functions provide straightforward XML parsing and XPath queries.

Table F.46. `xml2` Functions

Function	Description
<code>xml_valid (document text) → boolean</code>	Parses the given document and returns true if the document is well-formed XML. (Note: this is an alias for the standard Postgres Pro function <code>xml_is_well_formed()</code> . The name <code>xml_valid()</code> is technically incorrect since validity and well-formedness have different meanings in XML.)
<code>xpath_string (document text, query text) → text</code>	Evaluates the XPath query on the supplied document, and casts the result to <code>text</code> .
<code>xpath_number (document text, query text) → real</code>	Evaluates the XPath query on the supplied document, and casts the result to <code>real</code> .
<code>xpath_bool (document text, query text) → boolean</code>	Evaluates the XPath query on the supplied document, and casts the result to <code>boolean</code> .
<code>xpath_nodeSet (document text, query text, toptag text, itemtag text) → text</code>	Evaluates the query on the document and wraps the result in XML tags. If the result is multi-valued, the output will look like: <pre><toptag> <itemtag>Value 1 which could be an XML fragment</itemtag> <itemtag>Value 2....</itemtag> </toptag></pre> If either <code>toptag</code> or <code>itemtag</code> is an empty string, the relevant tag is omitted.
<code>xpath_nodeSet (document text, query text, itemtag text) → text</code>	Like <code>xpath_nodeSet (document, query, toptag, itemtag)</code> but result omits <code>toptag</code> .
<code>xpath_nodeSet (document text, query text) → text</code>	Like <code>xpath_nodeSet (document, query, toptag, itemtag)</code> but result omits both tags.
<code>xpath_list (document text, query text, separator text) → text</code>	Evaluates the query on the document and returns multiple values separated by the specified separator, for example <code>Value 1,Value 2,Value 3</code> if <code>separator</code> is <code>,</code> .
<code>xpath_list (document text, query text) → text</code>	This is a wrapper for the above function that uses <code>,</code> as the separator.

F.72.3. xpath_table

`xpath_table(text key, text document, text relation, text xpaths, text criteria)` returns setof record

`xpath_table` is a table function that evaluates a set of XPath queries on each of a set of documents and returns the results as a table. The primary key field from the original document table is returned as the first column of the result so that the result set can readily be used in joins. The parameters are described in [Table F.47](#).

Table F.47. xpath_table Parameters

Parameter	Description
<i>key</i>	the name of the “key” field — this is just a field to be used as the first column of the output table, i.e., it identifies the record from which each output row came (see note below about multiple values)
<i>document</i>	the name of the field containing the XML document
<i>relation</i>	the name of the table or view containing the documents
<i>xpaths</i>	one or more XPath expressions, separated by
<i>criteria</i>	the contents of the WHERE clause. This cannot be omitted, so use <code>true</code> or <code>1=1</code> if you want to process all the rows in the relation

These parameters (except the XPath strings) are just substituted into a plain SQL SELECT statement, so you have some flexibility — the statement is

```
SELECT <key>, <document> FROM <relation> WHERE <criteria>
```

so those parameters can be *anything* valid in those particular locations. The result from this SELECT needs to return exactly two columns (which it will unless you try to list multiple fields for key or document). Beware that this simplistic approach requires that you validate any user-supplied values to avoid SQL injection attacks.

The function has to be used in a FROM expression, with an AS clause to specify the output columns; for example

```
SELECT * FROM
xpath_table('article_id',
            'article_xml',
            'articles',
            '/article/author|/article/pages|/article/title',
            'date_entered > '2003-01-01' ')
AS t(article_id integer, author text, page_count integer, title text);
```

The AS clause defines the names and types of the columns in the output table. The first is the “key” field and the rest correspond to the XPath queries. If there are more XPath queries than result columns, the extra queries will be ignored. If there are more result columns than XPath queries, the extra columns will be NULL.

Notice that this example defines the `page_count` result column as an integer. The function deals internally with string representations, so when you say you want an integer in the output, it will take the string representation of the XPath result and use Postgres Pro input functions to transform it into an integer (or whatever type the AS clause requests). An error will result if it can't do this — for example if the result is empty — so you may wish to just stick to `text` as the column type if you think your data has any problems.

The calling SELECT statement doesn't necessarily have to be just `SELECT *` — it can reference the output columns by name or join them to other tables. The function produces a virtual table with which you can perform any operation you wish (e.g., aggregation, joining, sorting etc.). So we could also have:

```
SELECT t.title, p.fullname, p.email
FROM xpath_table('article_id', 'article_xml', 'articles',
                '/article/title|article/author/@id',
                'xpath_string(article_xml, '/article/@date') > ''2003-03-20'' ')
  AS t(article_id integer, title text, author_id integer),
  tblPeopleInfo AS p
WHERE t.author_id = p.person_id;
```

as a more complicated example. Of course, you could wrap all of this in a view for convenience.

F.72.3.1. Multivalued Results

The `xpath_table` function assumes that the results of each XPath query might be multivalued, so the number of rows returned by the function may not be the same as the number of input documents. The first row returned contains the first result from each query, the second row the second result from each query. If one of the queries has fewer values than the others, null values will be returned instead.

In some cases, a user will know that a given XPath query will return only a single result (perhaps a unique document identifier) — if used alongside an XPath query returning multiple results, the single-valued result will appear only on the first row of the result. The solution to this is to use the key field as part of a join against a simpler XPath query. As an example:

```
CREATE TABLE test (
  id int PRIMARY KEY,
  xml text
);

INSERT INTO test VALUES (1, '<doc num="C1">
<line num="L1"><a>1</a><b>2</b><c>3</c></line>
<line num="L2"><a>11</a><b>22</b><c>33</c></line>
</doc>');

INSERT INTO test VALUES (2, '<doc num="C2">
<line num="L1"><a>111</a><b>222</b><c>333</c></line>
<line num="L2"><a>111</a><b>222</b><c>333</c></line>
</doc>');

SELECT * FROM
  xpath_table('id','xml','test',
              '/doc/@num|/doc/line/@num|/doc/line/a|/doc/line/b|/doc/line/c',
              'true')
  AS t(id int, doc_num varchar(10), line_num varchar(10), val1 int, val2 int, val3 int)
WHERE id = 1 ORDER BY doc_num, line_num
```

id	doc_num	line_num	val1	val2	val3
1	C1	L1	1	2	3
1		L2	11	22	33

To get `doc_num` on every line, the solution is to use two invocations of `xpath_table` and join the results:

```
SELECT t.*,i.doc_num FROM
  xpath_table('id', 'xml', 'test',
              '/doc/line/@num|/doc/line/a|/doc/line/b|/doc/line/c',
              'true')
  AS t(id int, line_num varchar(10), val1 int, val2 int, val3 int),
  xpath_table('id', 'xml', 'test', '/doc/@num', 'true')
  AS i(id int, doc_num varchar(10))
WHERE i.id=t.id AND i.id=1
ORDER BY doc_num, line_num;
```

```
id | line_num | val1 | val2 | val3 | doc_num
---+-----+-----+-----+-----+-----
 1 | L1       |    1 |    2 |    3 | C1
 1 | L2       |   11 |   22 |   33 | C1
(2 rows)
```

F.72.4. XSLT Functions

The following functions are available if libxslt is installed:

F.72.4.1. `xslt_process`

`xslt_process(text document, text stylesheet, text paramlist)` returns text

This function applies the XSL stylesheet to the document and returns the transformed result. The `paramlist` is a list of parameter assignments to be used in the transformation, specified in the form `a=1,b=2`. Note that the parameter parsing is very simple-minded: parameter values cannot contain commas!

There is also a two-parameter version of `xslt_process` which does not pass any parameters to the transformation.

F.72.5. Author

John Gray <jgray@azuli.co.uk>

Development of this module was sponsored by Torchbox Ltd. (www.torchbox.com). It has the same BSD license as Postgres Pro.

Appendix G. Postgres Pro Modules and Extensions Shipped as Individual Packages

This appendix contains Postgres Pro modules and extensions that are made available in Postgres Pro Standard as individual packages. These packages are listed in [Section 16.1.4.1](#), and the documentation for each module explains which package to choose to install it. [Appendix F](#) covers more modules and extensions included in the Postgres Pro Standard distribution. The `pg_portal_modify` extension is also shipped as an individual package (see [Section 16.1.4.1](#) for details).

G.1. `pgpro_pwr` — workload reports

The `pgpro_pwr` module is designed to discover most resource-intensive activities in your database. (PWR, pronounced like "power", is an abbreviation of Postgres Pro Workload Reporting.) This extension is based on Postgres Pro's [Statistics Collector](#) views and the `pgpro_stats` or `pg_stat_statements` extension.

Note

Although `pgpro_pwr` can work with the `pg_stat_statements` extension, it is recommended that you use the `pgpro_stats` extension since it provides statement plans, wait events sampling and load distribution statistics for databases, roles, client hosts and applications.

Below, use of `pgpro_stats` is assumed unless otherwise noted.

If you cannot use `pgpro_stats` for an observed database, but the `pg_stat_kcache` extension is available, `pgpro_pwr` can process `pg_stat_kcache` data, which also provides information about CPU resource usage of statements and filesystem load (*rusage*).

`pgpro_pwr` can obtain summary wait statistics from the `pg_wait_sampling` extension. When `pg_wait_sampling` is in use, `pgpro_pwr` will reset the wait sampling profile on every sample.

`pgpro_pwr` is based on cumulative statistics sampling. Each sample contains statistic increments for most active objects and queries since the time when the previous sample was taken, or more concisely, *since the previous sample*. This data is later used to generate reports.

`pgpro_pwr` provides functions to collect samples. Regular sampling allows building a report on the database workload in the past.

`pgpro_pwr` allows you to take explicit samples during batch processing, load testing, etc.

Any time a sample is taken, `pgpro_stats_statements_reset()` (see [pgpro_stats](#) for the function description) is called to ensure that statement statistics will not be lost when the statements count exceed `pgpro_stats.max` (see [Section G.2.7.1](#)). The report will also contain a section informing you of whether the count of captured statements in any sample reaches 90% of `pgpro_stats.max`.

`pgpro_pwr` installed on one Postgres Pro server can also collect statistics from other servers. This feature is useful for gathering workload statistics from hot standbys on the primary server. To benefit from it, make sure that all server names and connection strings are specified and that the `pgpro_pwr` server can connect to all databases on all servers.

G.1.1. `pgpro_pwr` Architecture

The extension consists of the following parts:

- *Historical repository* is a storage for sampling data. The repository is a set of extension tables.

Note

Among the rest, `pgpro_pwr` tables store query texts, which can contain sensitive information. So, for security reasons, restrict access to the repository as appropriate.

- *Sample management engine* comprises functions used to [take samples](#) and maintain the repository by removing obsolete sample data.
- *Report engine* comprises functions for [generating reports](#) based on data from the historical repository.
- *Administrative functions* allow you to create and manage [servers](#) and [baselines](#).

G.1.2. Prerequisites

The prerequisites assume that `pgpro_pwr`, which is usually installed in a *target* cluster, i.e., the cluster that you will mainly track the workload for, the extension can also collect performance data from other clusters.

G.1.2.1. For the `pgpro_pwr` Database

The `pgpro_pwr` extension depends on [PL/pgSQL](#) and the [dblink](#) extension.

G.1.2.2. For the Target Server

The target server must allow connections to all databases from the server where `pgpro_pwr` is running. To connect to the target server, provide a connection string where a particular database on this server is specified. This database is of high importance for `pgpro_pwr` since the functionality of the [pgpro_stats](#) or [pg_stat_statements](#) extensions will be provided through this database. Note, however, that `pgpro_pwr` will also connect to all the other databases on this server.

Optionally, for completeness of gathered statistics:

- If statement statistics are needed in reports, [pgpro_stats](#) must be installed and configured in the aforementioned database. The following settings may affect the completeness and accuracy of gathered statistics:

- `pgpro_stats.max`

Low setting of this parameter may cause some statement statistics to be wiped out before the sample is taken. A report will warn you if the value of `pgpro_stats.max` seems undersized.

- `pgpro_stats.track`

Avoid changing the default value of 'top' (note that the value of 'all' will affect the accuracy of %Total fields for statements-related sections of a report).

- Set the parameters of the Postgres Pro's [Statistics Collector](#) as follows:

```
track_activities = on
track_counts = on
track_io_timing = on
track_wal_io_timing = on    # Since PostgreSQL 14
track_functions = all/pl
```

G.1.3. Installation and Setup

`pgpro_pwr` is provided with Postgres Pro Standard as a separate pre-built package `pgpro-pwr-std-16` (for the detailed installation instructions, see [Chapter 16](#)).

Note

`pgpro_pwr` creates a bunch of database objects, so installation in a dedicated schema is recommended.

Although the use of `pgpro_pwr` with superuser privileges does not have any issues, superuser privileges are not necessary. So you can choose one of the following setup procedures depending on your configuration and security requirements or customize them to meet your needs:

G.1.3.1. Simple Setup

Use this setup procedure when `pgpro_pwr` is to be installed on the target cluster to only track its workload as superuser.

Create a schema for the `pgpro_pwr` installation and create the extension:

```
CREATE SCHEMA profile;
CREATE EXTENSION pgpro_pwr SCHEMA profile;
```

G.1.3.2. Complex Setup

Use this setup procedure when you intend to use `pgpro_pwr` for tracking workload on one or more servers and need to follow the principle of least privilege.

G.1.3.2.1. In the Target Server Database

Create a user for `pgpro_pwr` on the target server:

```
CREATE USER pwr_collector PASSWORD 'collector_pwd';
```

Make sure this user has permissions to connect to any database in the target cluster (by default, it is true) and that `pg_hba.conf` permits such a connection from the `pgpro_pwr` database host. Also, grant `pwr_collector` with membership in the `pg_read_all_stats` role and the `EXECUTE` privilege on the following functions:

```
GRANT pg_read_all_stats TO pwr_collector;
GRANT EXECUTE ON FUNCTION pgpro_stats_statements_reset TO pwr_collector;
GRANT EXECUTE ON FUNCTION pgpro_stats_totals_reset(text,bigint) TO pwr_collector;
```

Also ensure the `SELECT` privilege on the `pgpro_stats_archiver` view:

```
GRANT SELECT ON pgpro_stats_archiver TO pwr_collector;
```

G.1.3.2.2. In the `pgpro_pwr` Database

Create an unprivileged user:

```
CREATE USER pwr_user;
```

This user will be the owner of the extension schema and will collect samples.

Create a schema for the `pgpro_pwr` installation:

```
CREATE SCHEMA profile AUTHORIZATION pwr_user;
```

Grant the `USAGE` privilege on the schema where the `dblink` extension resides:

```
GRANT USAGE ON SCHEMA public TO pwr_user;
```

Create the extension using `pwr_user` account:

```
\c - pwr_user
CREATE EXTENSION pgpro_pwr SCHEMA profile;
```

Define the connection parameters of the target server for `pgpro_pwr`. For example:

```
SELECT profile.create_server('target_server_name','host=192.168.1.100 dbname=postgres  
port=5432');
```

The connection string provided will be used in the `dblink_connect()` call while executing the `take_sample()` function.

Note

Connection strings are stored in a `pgpro_pwr` table in clear-text form. Make sure no other database users can access tables of the `pgpro_pwr` extension.

G.1.3.3. Setting Up `pgpro_pwr` Roles

Up to three roles can be distinguished when `pgpro_pwr` is in operation:

- The *pgpro_pwr owner* role is the owner of the `pgpro_pwr` extension.
- The *collecting role* is used by `pgpro_pwr` to connect to databases and collect statistics.
- The *reporting role* is used to generate reports.

If all the actions with `pgpro_pwr` are performed by the superuser role `postgres`, you can skip most of the setup explained below.

G.1.3.3.1. The `pgpro_pwr` Owner

This role can be used to perform all actions related to `pgpro_pwr`. This role will have access to server connection strings, which may contain passwords. You should use this role to call the `take_sample()` function. The `dblink` extension is needed for this user.

Consider an example assuming each extension in its own schema:

```
\c postgres postgres
CREATE SCHEMA dblink;
CREATE EXTENSION dblink SCHEMA dblink;
CREATE USER pwr_usr with password 'pwr_pwd';
GRANT USAGE ON SCHEMA dblink TO pwr_usr;
CREATE SCHEMA profile AUTHORIZATION pwr_usr;
\c postgres pwr_usr
CREATE EXTENSION pgpro_pwr SCHEMA profile;
```

G.1.3.3.2. The Collecting Role

This role should be used by `pgpro_pwr` to connect to databases and collect statistics. Unprivileged users cannot open connections using `dblink` without a password, so you need to provide the password in the connection string for each server. This role should have access to all supported statistics extensions. It should also be able to perform a reset of statistics extensions.

Consider an example. If you use `pgpro_stats` to collect statistics, set up the collecting role as follows:

```
\c postgres postgres
CREATE SCHEMA pgps;
CREATE EXTENSION pgpro_stats SCHEMA pgps;
CREATE USER pwr_collector with password 'collector_pwd';
GRANT pg_read_all_stats TO pwr_collector;
GRANT USAGE ON SCHEMA pgps TO pwr_collector;
GRANT EXECUTE ON FUNCTION pgps.pgpro_stats_statements_reset TO pwr_collector;
```

If you use `pg_stat_statements` to collect statistics, set up the collecting role as follows:

```
\c postgres postgres
CREATE SCHEMA pgss;
CREATE SCHEMA pgsk;
```

```
CREATE SCHEMA pgws;  
CREATE EXTENSION pg_stat_statements SCHEMA pgss;  
CREATE EXTENSION pg_stat_kcache SCHEMA pgsk;  
CREATE EXTENSION pg_wait_sampling SCHEMA pgws;  
CREATE USER pwr_collector with password 'collector_pwd';  
GRANT pg_read_all_stats TO pwr_collector;  
GRANT USAGE ON SCHEMA pgss TO pwr_collector;  
GRANT USAGE ON SCHEMA pgsk TO pwr_collector;  
GRANT USAGE ON SCHEMA pgws TO pwr_collector;  
GRANT EXECUTE ON FUNCTION pgss.pg_stat_statements_reset TO pwr_collector;  
GRANT EXECUTE ON FUNCTION pgsk.pg_stat_kcache_reset TO pwr_collector;  
GRANT EXECUTE ON FUNCTION pgws.pg_wait_sampling_reset_profile TO pwr_collector;
```

Now you should set up a connection string pointing to the database with statistics extensions installed:

```
\c postgres pwr_usr  
SELECT profile.set_server_connstr('local','dbname=postgres port=5432 host=localhost  
user=pwr_collector password=collector_pwd');
```

Password authentication must be configured in the `pg_hba.conf` file for the `pwr_collector` user.

Obviously, the collecting role should be properly configured on all servers observed by `pgpro_pwr`.

Now you should be able to call `take_sample()` using the `pwr_usr` role:

```
\c postgres pwr_usr  
SELECT * FROM take_sample();
```

And now it's time to configure the scheduler (in our example, the `crontab` command of the `postgres` user):

```
*/30 * * * *    psql -U pwr_usr -d postgres -c 'SELECT profile.take_sample()' > /dev/  
null 2>&1
```

Note that you can use the Postgres Pro password file to store passwords.

G.1.3.3.3. The Reporting Role

Any user can build a `pgpro_pwr` report. The minimal privileges needed to generate `pgpro_pwr` reports are granted to the `public` role. However a full report, with query texts, is only available to the member of the `pg_read_all_stats` role. Anyway, the reporting role cannot access server connection strings, so it cannot get the passwords of servers.

G.1.3.3.4. Setting Extension Parameters

In `postgresql.conf`, you can define the following `pgpro_pwr` parameters:

`pgpro_pwr.max` (integer)

Number of top objects (statements, relations, etc.) to be reported in each sorted report table. This parameter affects the size of a sample.

The default value is 20.

`pgpro_pwr.max_sample_age` (integer)

Retention time of the sample, in days. Samples aged `pgpro_pwr.max_sample_age` days and older are automatically deleted on the next `take_sample()` call.

The default value is 7 days.

`pgpro_pwr.max_query_length` (integer)

Maximum query length allowed in reports. All queries in a report will be truncated to `pgpro_pwr.max_query_length` characters.

The default value is 20 000 characters.

`pgpro_pwr.track_sample_timings` (boolean)

Enables collecting detailed timing statistics of `pgpro_pwr`'s own sampling procedures. Set this parameter to diagnose why sampling functions run slowly. Collected timing statistics will be available in the `v_sample_timings` view.

The default value is `off`.

`pgpro_pwr.statements_reset` (boolean)

Controls the `pgpro_stats/pg_stat_statements` statistics reset during taking a sample. Allows you not to reset the statistics during taking a sample due to new techniques employed. When disabled, `pgpro_pwr` will track statement evictions using the value of the `calls` field. However this method does not completely prevent statistics loss. `pg_stat_statements` v1.11 and `pgpro_stats` v1.8 contain time tracking abilities that can reduce the possible data loss. When this setting is disabled, you can temporarily enable it in a session if you want to sometimes perform a reset of `pgpro_stats/pg_stat_statements`.

The default value is `on`.

`pgpro_pwr.relsizes_collect_mode` (text)

Defines the mode of collecting relation sizes. Possible values:

- `off` — collection of relation sizes is based on `pg_class`. Although the relation sizes collected this way are rough, their collection consumes almost no resources.
- `on` — accurate relation sizes are collected for each sample using the `pg_relation_size()` function, which requires a lock on the table and is pretty resource intensive.
- `schedule` — accurate relation sizes are collected in the size-collection window, defined for each server.

The default value is `off`.

G.1.4. Managing Servers

Once installed, `pgpro_pwr` creates one enabled `local` server for the current cluster. If a server is *enabled*, `pgpro_pwr` includes it in sampling when no server is explicitly specified (see `take_sample()` for details). A server that is not enabled is referred to as *disabled*.

The default connection string for a local node contains only `dbname` and `port` parameters. The values of these parameters are taken from the connection used to create the extension. You can change the server connection string using the `set_server_connstr()` function when needed.

G.1.4.1. Server Management Functions

Use the following `pgpro_pwr` functions for server management:

```
create_server(server name, connstr text, enabled boolean DEFAULT TRUE, max_sample_age
integer DEFAULT NULL description text DEFAULT NULL)
```

Creates a server definition.

Arguments:

- `server` — server name. Must be unique.
- `connstr` — connection string. Must contain all the necessary settings to connect from `pgpro_pwr` server to the target server database.
- `enabled` — set to include the server in sampling by the `take_sample()` function without arguments.

- *max_sample_age* — retention time of the sample. Overrides the global `pgpro_pwr.max_sample_age` setting for this server.
- *description* — server description text, to be included in reports.

Here is an example of how to create a server definition:

```
SELECT profile.create_server('omega','host=192.168.1.100 dbname=postgres  
port=5432');
```

`drop_server(server name)`

Drops a server and all its samples.

`set_server_description(server name description text)`

Sets a new server description.

`set_server_subsampling(server name, subsample_enabled boolean, min_query_duration interval, min_xact_duration interval, min_xact_age integer, min_idle_xact_dur interval hour to second)`

Defines subsample settings for a server.

Arguments:

- *server* — server name.
- *subsample_enabled* — defines whether subsampling is enabled for the server, that is, whether `take_subsample()` function should actually take a subsample.
- *min_query_duration* — the query duration threshold.
- *min_xact_duration* — the transaction duration threshold.
- *min_xact_age* — the transaction age threshold.
- *min_idle_xact_dur_age* — the idle transaction threshold.

`enable_server(server name)`

Includes a server in sampling by the `take_sample()` function without arguments.

`disable_server(server name)`

Excludes a server from sampling by the `take_sample()` function without arguments.

`rename_server(server name, new_name name)`

Renames a server.

`set_server_max_sample_age(server name, max_sample_age integer)`

Sets the retention period for a server (in days). To reset the server retention, set the value of *max_sample_age* to NULL.

`set_server_db_exclude(server name, exclude_db name[])`

Excludes a list of databases on a server from sampling. Use when `pgpro_pwr` is unable to connect to some databases in a cluster (for example, in Amazon RDS instances).

`set_server_connstr(server name, server_connstr text)`

Sets the connection string for a server.

`set_server_setting(server name, setting text, value jsonb)`

Fine-tunes settings of the server statistics collection. `collect*` settings control which statistics should be collected, and *value* for these settings accepts boolean values, with the default equal to `true`. Available settings:

- `collect_pg_stat_statement` — collect statement statistics using `pg_stat_statements` and `pg_stat_kcache` extensions.
- `collect_pg_wait_sampling` — collect wait event statistics using the `pg_wait_sampling` extension.
- `collect_objects` — collect all the schema object statistics, that is, tables, indexes, and functions, from `pg_stat_*` views.
- `collect_relations` — collect statistics on tables and indexes from `pg_stat_*` views.
- `collect_functions` — collect statistics on user functions from the `pg_stat_user_functions` view.
- `collect_vacuum_stats` — collect the extended vacuum statistics.

`show_server_settings(server name)`

Returns the statistics collection settings for the specified server.

`show_servers()`

Displays the list of configured servers.

G.1.5. Managing Samples

A *sample* contains the database workload statistics since the previous sample

G.1.5.1. Sampling Functions

The following `pgpro_pwr` functions relate to sampling:

`take_sample()`

`take_sample(server name [, skip_sizes boolean])`

Takes samples.

If the parameter is omitted, the function takes a sample on each enabled server. Servers are accessed for sampling sequentially, one by one. The function returns a table with the following columns:

- `server` — server name.
- `result` — result of taking the sample. Can be OK if the sample was taken successfully or contain the error trace text in case of exception.
- `elapsed` — time elapsed while the sample was taken.

If called with the parameter, the function takes a sample on the specified server even if this server is disabled. Use when you need different sampling frequencies on specific servers. Returns 0 on success.

Arguments:

- `server` — server name.
- `skip_sizes` — if omitted or set to null, the size-collection policy applies; if `false`, relation sizes are collected; if `true`, the collection of relation sizes is skipped.

`take_sample_subset([sets_cnt integer, current_set integer])`

Takes a sample on each server in a subset of servers. Use to take samples on servers in parallel if you have many enabled servers. Although PL/pgSQL does not support parallel execution, you can call this function in parallel sessions. This function returns the same type as `take_sample()`. If both parameters are omitted, the function behaves like the `take_sample()` function, i.e., it takes a sample on all enabled servers one by one.

Arguments:

- *sets_cnt* — number of subsets to divide all enabled servers into.
- *current_set* — number of the subset to collect samples for. Takes values from 0 through *sets_cnt* - 1. For the specified subset, samples are collected as usual, server by server.

If a reset of statistics since the previous sample was detected, `pgpro_pwr` treats corresponding absolute values as differentials; however, the accuracy will be affected anyway.

```
show_samples([server name,] [days integer])
```

Returns a table with information on server samples (`local` server is assumed if *server* is omitted) for the last *days* days (all existing samples are assumed if omitted). This table has the following columns:

- *sample* — sample identifier.
- *sample_time* — time when this sample was taken.
- *dbstats_reset* — NULL or the statistics reset timestamp of the `pg_stat_database` view if the statistics were reset since the previous sample.
- *clustats_reset* — NULL or the statistics reset timestamp of the `pg_stat_bgwriter` view if the statistics were reset since the previous sample.
- *archstats_reset* — NULL or the statistics reset timestamp of the `pg_stat_archiver` view if the statistics were reset since the previous sample.

Sampling functions also maintain the server repository by deleting obsolete samples and baselines according to the retention policy.

G.1.5.2. Taking Samples

To take samples for all enabled servers, call the `take_sample()` function. Usually, one or two samples per hour is sufficient. You can use a cron-like tool to schedule sampling. Here is an example for a 30-minute sampling period:

```
*/30 * * * * psql -c 'SELECT profile.take_sample()' &> /dev/null
```

However, the results of such a call are not checked for errors. In a production environment, function results can be used for monitoring. This function returns OK for all servers with successfully taken samples and shows error text for failed servers:

```
SELECT * FROM take_sample();
  server  |                                     result
  |      elapsed
-----+-----
ok_node  | OK
  | 00:00:00.48
fail_node | could not establish connection
+| 00:00:00
          | SQL statement "SELECT dblink_connect('server_connection',server_connstr)"
+|
          | PL/pgSQL function take_sample(integer) line 69 at PERFORM
+|
          | PL/pgSQL function take_sample_subset(integer,integer) line 27 at
assignment+|
          | SQL function "take_sample" statement 1
+|
          | FATAL:  database "postgresno" does not exist
  |
(2 rows)
```

G.1.5.3. Sample Retention Policy

You can define sample retention at the following levels:

1. *Global*

The value of the `pgpro_pwr.max_sample_age` parameter in the `postgresql.conf` file defines a common retention setting, which is effective if none of other related settings are defined.

2. *Server*

Specifying the `max_sample_age` parameter while creating a server or calling the `set_server_max_sample_age(server, max_sample_age)` function for an existing server defines the retention for the server. A server retention setting overrides `pgpro_pwr.max_sample_age` for a specific server.

3. *Baseline*

A [baseline](#) created overrides all the other retention periods for included samples.

G.1.6. Managing the Collection of Relation Sizes

It may take considerable time to collect sizes of all relations in a database by Postgres Pro relation-size functions. Besides, those functions require `AccessExclusiveLock` on a relation. However, it may be sufficient for you to collect relation sizes on a daily basis. `pgpro_pwr` allows you to skip collecting relation sizes by defining the *size-collection policy* for servers. The policy defines:

- A daily window when the collection of relation sizes is permitted.
- A minimum gap between two samples with relation sizes collected.

When the size-collection policy is defined, sampling functions collect relation sizes only when the sample is taken in the defined window and the previous sample with sizes is older than the gap. The following function defines this policy:

```
set_server_size_sampling(server name, window_start time with time zone DEFAULT NULL,  
window_duration interval hour to second DEFAULT NULL, sample_interval interval day to  
minute DEFAULT NULL, collect_mode text DEFAULT NULL)
```

Defines the size-collection policy for a server.

Arguments:

- `server` — server name.
- `window_start` — start time of the size-collection window.
- `window_duration` — duration of the size-collection window.
- `sample_interval` — minimum time gap between two samples with relation sizes collected.
- `collect_mode` — when set to `off`, which is the default for new installations, relation sizes are collected from `pg_class`, when set to `on`, relation sizes are collected using the `pg_relation_size()` function, when set to `schedule`, `pgpro_pwr` collects the relation size in the size-collection window. This parameter overrides the `relnsize_collect_mode` extension parameter. Upgrading from a previous version sets the value of this parameter to `on` or `schedule`, so the previous behavior does not change.

Note

When you build a report between samples either of which lacks relation-size data, relation-growth sections will be based on `pg_class.relpages` data. However, you can expand the report interval bounds to the nearest samples with relation sizes collected using the `with_growth` parameter of [report generation functions](#); this makes the growth data more accurate.

Relation sizes are needed to calculate sequentially scanned volume for tables and explicit vacuum load for indexes.

Example:

```
SELECT set_server_size_sampling('local','23:00+03',interval '2 hour',interval '8 hour',
'schedule');
```

The `show_servers_size_sampling` function shows size collection policies for all servers:

```
postgres=# SELECT * FROM show_servers_size_sampling();
 server_name | window_start | window_end | window_duration | sample_interval |
limited_collection
-----+-----+-----+-----+-----+-----
+-----+
 local      | 23:00:00+03 | 01:00:00+03 | 02:00:00        | 08:00:00        | t
```

G.1.7. Managing Subsamples

Some performance-related data available in Postgres Pro is not cumulative. For example, the most often used data about session states is available through the [pg_stat_activity](#) view and can only be obtained with frequent samples. However, the `take_sample()` function is heavy and can take considerable amount of time. So it is not suitable for collecting session state data.

The *subsample* feature provides a new fast `take_subsample()` function. It can be used to collect relatively fast changing data. Every subsample is bound to the next regular sample and is deleted by the retention policy together with it.

The subsample feature can be used to capture the most interesting session states:

- Long running queries
- Long transactions
- Aged transactions, that is, those that hold a snapshot behind a lot of other transactions
- Transactions being in an idle state for a long time

G.1.7.1. Subsampling Functions

The following `pgpro_pwr` functions relate to subsampling:

```
take_subsample()
take_subsample(server name)
```

If the parameter is omitted, the function takes a subsample on each *enabled* server with subsampling enabled (see [set_server_subsampling](#) for details). Server subsamples are taken sequentially, one by one. The function returns a table with the following columns:

- `server` — server name.
- `result` — result of taking the subsample. Can be `OK` if the subsample was taken successfully or contain the error text in case of exception.
- `elapsed` — time elapsed while the subsample was taken.

This tabular return format makes it easy to control subsample creation using an SQL query.

If called with the parameter, the function takes a subsample for the specified server. Use when you need different subsampling frequencies on servers or if you want to take an explicit subsample on a specific server.

Arguments:

- *server* — server name.

Note

Trying to take a subsample during taking a sample fails.

`take_subsample_subset([sets_cnt integer], [current_set integer])`

Takes subsamples for a subset of enabled servers with subsampling enabled. Although subsamples should be fast enough for serial processing, subsamples can be taken in parallel, like regular samples. This function returns the same type as `take_subsample()`. If both parameters are omitted, the function behaves like the `take_subsample()` function.

Arguments:

- *sets_cnt* — number of server subsets.
- *current_set* — the subset to process. Takes values from 0 through *sets_cnt* - 1. For the specified subset, subsamples are collected as usual, server by server.

G.1.7.2. Configuring the Subsample Feature

The following settings affect the subsample behaviour:

- `pgpro_pwr.subsample_enabled` — defines whether the `take_subsample()` function should actually take a subsample.
- `pgpro_pwr.min_query_duration` — the long running query threshold.
- `pgpro_pwr.min_xact_duration` — the long transaction threshold.
- `pgpro_pwr.min_xact_age` — the transaction age threshold.
- `pgpro_pwr.min_idle_xact_dur_age` — the idle transaction threshold.

The subsample behavior can be defined at the server level using the `set_server_subsampling` function.

The last observed session state is saved in the repository when either of the following threshold-related events happens:

- During query execution, the difference between `now()` and the `query_start` exceeds the `pgpro_pwr.min_query_duration` threshold.
- During a transaction, the difference between `now()` and the `xact_start` exceeds the `pgpro_pwr.min_xact_duration` threshold.
- During a transaction, the `age(backend_xmin)` exceeds the `pgpro_pwr.min_xact_age` threshold.
- During a transaction in a state `idle in transaction` or `idle in transaction (aborted)`, the difference between `now()` and the `state_change` exceeds the `pgpro_pwr.min_idle_xact_duration` threshold.

See [Chapter 26](#) for details of the mentioned fields. Every subsample can hold at most `pgpro_pwr.max` entries for every threshold type.

G.1.7.3. Scheduling Subsamples

Subsamples are fast enough to take them quite often. However usually you do not need more than 2-4 subsamples per minute. Obviously the subsample frequency depends on the shortest used duration of a threshold setting.

Cron only allows one call per minute, so some effort is needed to schedule more frequent subsamples. For example, the `\watch psql` command can be used:

```
echo "select take_subsample(); \watch 15" | psql &> /dev/null
```

The `psql` call can be wrapped in the `systemd` service like this:

```
Description=pgpro_pwr subsampling unit
[Unit]

[Service]
Type=simple
ExecStart=/bin/sh -c 'echo "select take_subsample(); \\watch 15" | /path/to/psql -go /dev/null'
User=postgres
Group=postgres

[Install]
WantedBy=multi-user.target
```

G.1.8. Managing Baselines

A *baseline* is a named sequence of samples that has its own retention setting. A baseline can be used as a sample interval in report generation functions. An undefined baseline retention means infinite retention. Use baselines to save information about the database workload for a certain time interval.

G.1.8.1. Baseline Management Functions

Use the following `pgpro_pwr` functions for baseline management:

```
create_baseline([server name,] baseline varchar(25), start_id integer, end_id integer [,
days integer])
create_baseline([server name,] baseline varchar(25), time_range tstzrange [, days in-
teger])
```

Creates a baseline.

Arguments:

- *server* — server name. `local` sever is assumed if omitted.
- *baseline* — baseline name. Must be unique for a server.
- *start_id* — identifier of the first sample in the baseline.
- *end_id* — identifier of the last sample in the baseline.
- *time_range* — time interval for the baseline. The baseline will include all samples for the minimal interval that covers *time_range*.
- *days* — baseline retention time, defined in integer days since `now()`. Omit or set to null for infinite retention.

```
drop_baseline([server name,] baseline varchar(25))
```

Drops a baseline. For the meaning and usage details of function arguments, see [create_baseline](#). Dropping a baseline does not mean dropping all its samples immediately. The baseline retention just no longer applies to them.

```
keep_baseline([server name,] baseline varchar(25) [, days integer])
```

Changes the retention of a baseline. For the meaning and usage details of function arguments, see [create_baseline](#). Omit the *baseline* parameter or pass null to it to change the retention of all existing baselines.

```
show_baselines([server name])
```

Displays existing baselines. Call `show_baselines` to get information about the baselines, such as names, sampling intervals and retention periods. `local` sever is assumed if the *server* parameter is omitted.

G.1.9. Data Export and Import

Collected samples can be exported from one instance of the `pgpro_pwr` extension and then loaded into another one. This feature helps you to move server data from one instance to another or to send collected data to your support team.

G.1.9.1. Data Export

The `export_data` function exports data to a regular table. You can use any method available to export this table from your database. For example, you can use the `\copy` meta-command of `psql` to obtain a single `csv` file:

```
postgres=# \copy (select * from export_data()) to 'export.csv'
```

G.1.9.2. Data Import

Since data can only be imported from a local table, first, load the data you exported. Using the `\copy` meta-command again:

```
postgres=# CREATE TABLE import (section_id bigint, row_data json);
CREATE TABLE
postgres=# \copy import from 'export.csv'
COPY 6437
```

Now you can import the data by providing the `import` table to the `import_data` function:

```
postgres=# SELECT * FROM import_data('import');
```

After successful import, you can drop the `import` table.

Note

If server data is imported for the first time, your local `pgpro_pwr` servers with matching names will cause a conflict during import. To avoid this, you can temporarily rename such servers or you can specify the server name prefix for import operations. However, during import of new data for already imported servers, they are matched by system identifiers, so feel free to rename imported servers. Also keep in mind that `pgpro_pwr` sets servers being imported to the *disabled* state for `take_sample()` to bypass them.

G.1.9.3. Export and Import Functions

Use these functions to export or import data:

```
export_data([server name, [min_sample_id integer,] [max_sample_id integer,]] [, obfuscate_queries boolean])
```

Exports collected data.

Arguments:

- `server` — server name. All configured servers are assumed if omitted.
- `min_sample_id`, `max_sample_id` — sample identifiers to bound the export (inclusive). If `min_sample_id` is omitted or set to null, all samples until `max_sample_id` sample are exported; if `max_sample_id` is omitted or set to null, all samples since `min_sample_id` sample are exported.
- `obfuscate_queries` — if `true`, query texts are exported as MD5 hash.

```
import_data(data regclass [, server_name_prefix text])
```

Imports previously exported data. Returns the number of actually loaded rows in `pgpro_pwr` tables.

Arguments:

- *data* is the name of the table containing import data.
- *server_name_prefix* specifies the server name prefix for the import operation. It can be used to avoid name conflicts.

G.1.10. Report Generation Functions

pgpro_pwr reports are generated in HTML format by reporting functions. The following types of reports are available:

- *Regular reports* provide statistics on the workload for an interval.
- *Differential reports* provide statistics on the same objects for two intervals. Corresponding values are located next to each other, which makes it easy to compare the workloads.

Reporting functions take sample identifiers, baselines or time ranges to determine the intervals. For time ranges, these are the minimal intervals that cover the ranges.

G.1.10.1. Regular Reports

Use these functions to generate regular reports:

```
get_report([server name,] start_id integer, end_id integer [, description text [,
with_growth boolean [, db_exclude name[]]])
get_report([server name,] time_range tstzrange [, description text [, with_growth boolean
[, db_exclude name[]]])
get_report([server name,] baseline varchar(25) [, description text [, with_growth boolean
[, db_exclude name[]]])
```

Generates a regular report defined by the arguments.

Arguments:

- *server* — server name. `local` sever is assumed if omitted.
- *start_id* — identifier of the interval starting sample.
- *end_id* — identifier of the interval ending sample.
- *baseline* — baseline name.
- *time_range* — time range.
- *description* — short text to be included in the report as its description.
- *with_growth* — flag requesting interval expansion to the nearest bounds with data on relation growth available. The default value is `false`.
- *db_exclude* — the database exclusion list. Lists databases to be excluded from all report tables having the `Database` column. Use to hide some databases in the report.

```
get_report_latest([server name,])
get_report_latest([server name [, db_exclude name[]]])
```

Generates a regular report for two latest samples.

Arguments:

- *server* — server name. `local` sever is assumed if omitted.
- *db_exclude* — the database exclusion list. Lists databases to be excluded from all report tables having the `Database` column. Use to hide some databases in the report.

G.1.10.2. Differential Reports

Use this function to generate differential reports:

Postgres Pro Modules and Extensions Shipped as Individual Packages

```
get_diffreport([server name,] start1_id integer, end1_id integer, start2_id integer,
end2_id integer [, description text [, with_growth boolean [, db_exclude name[]]])
get_diffreport([server name,] time_range1 tstzrange, time_range2 tstzrange [, description
text [, with_growth boolean [, db_exclude name[]]])
get_diffreport([server name,] baseline1 varchar(25), baseline2 varchar(25) [, description
text [, with_growth boolean [, db_exclude name[]]])
get_diffreport([server name,] baseline1 varchar(25), time_range2 tstzrange [, description
text [, with_growth boolean[, db_exclude name[]]])
get_diffreport([server name,] time_range1 tstzrange, baseline2 varchar(25) [, description
text [, with_growth boolean[, db_exclude name[]]])
get_diffreport([server name,] start1_id integer, end1_id integer, baseline2 varchar(25)
[, description text [, with_growth boolean[, db_exclude name[]]])
get_diffreport([server name,] baseline1 varchar(25), start2_id integer, end2_id integer
[, description text [, with_growth boolean[, db_exclude name[]]])
```

Generates a differential report for two intervals. The combinations of arguments provide possible ways to specify the two intervals.

Arguments:

- *server* — server name. `local` sever is assumed if omitted.
- *start1_id*, *end1_id* — identifiers of the starting and ending samples for the first interval.
- *start2_id*, *end2_id* — identifiers of the starting and ending samples for the second interval.
- *baseline1* — baseline name for the first interval.
- *baseline2* — baseline name for the second interval.
- *time_range1* — time range for the first interval.
- *time_range2* — time range for the second interval.
- *description* — short text to be included in the report as its description.
- *with_growth* — flag requesting interval expansion to the nearest bounds with data on relation growth available. The default value is `false`.
- *db_exclude* — the database exclusion list. Lists databases to be excluded from all report tables having the `Database` column. Use to hide some databases in the report.

G.1.10.3. Report Generation Example

Generate a report for the `local` server and interval defined by samples:

```
psql -Aqtc "SELECT profile.get_report(480,482)" -o report_480_482.html
```

For any other server, provide its name:

```
psql -Aqtc "SELECT profile.get_report('omega',12,14)" -o report_omega_12_14.html
```

Generate a report using time ranges:

```
psql -Aqtc "SELECT profile.get_report(tstzrange('2020-05-13 11:51:35+03','2020-05-13
11:52:18+03'))" -o report_range.html
```

Generate a relative time-range report:

```
psql -Aqtc "SELECT profile.get_report(tstzrange(now() - interval '1 day',now()))" -o
report_last_day.html
```

G.1.11. pgpro_pwr Report Sections

Each `pgpro_pwr` report is divided into sections, described below. The number of top objects reported in each sorted report table is specified by the `pgpro_pwr.max` parameter.

Almost every item in the report can be accentuated by a single mouse click. The accentuated item will be instantly highlighted in all report sections, making it easy to find. The attributes identifying the item will appear in the bottom-right corner of the page. For example, if you click on a database name in the “Database statistics” report table, you can notice a small table with the database attributes in the bottom-right corner of the page.

When you scroll down the report, its table of contents will be available on the right side of the page. It can be hidden with a single mouse click on the “content” tag.

A substring-based filter is also available that helps limit the report contents to particular objects based on a substring. Specifically, substring-based filtering is applied to query texts.

G.1.11.1. Server statistics

Tables in this section of a `pgpro_pwr` report are described below.

The report table “Database statistics” provides per-database statistics for the report interval. The statistics are based on the `pg_stat_database` view. [Table G.1](#) lists columns of this report table.

Table G.1. Database statistics

Column	Description	Field/Calculation
Database	Database name	<code>datname</code>
Commits	Number of committed transactions	<code>xact_commit</code>
Rollbacks	Number of rolled back transactions	<code>xact_rollback</code>
Deadlocks	Number of deadlocks detected	<code>deadlocks</code>
Checksum Failures	Number of data page checksum failures detected in this database. This field is only shown if any checksum failures were detected in this database during the report interval.	<code>checksum_failures</code>
Checksums Last	Time at which the last data page checksum failure was detected in this database. This field is only shown if any checksum failures were detected in this database during the report interval.	<code>checksum_last_failure</code>
Hit%	Buffer cache hit ratio, i.e., percentage of pages fetched from buffers in all pages fetched	
Read	Number of disk blocks read in this database	<code>blks_read</code>
Hit	Number of times disk blocks were found already in the buffer cache	<code>blks_hit</code>
Ret	Number of returned tuples	<code>tup_returned</code>
Fet	Number of fetched tuples	<code>tup_fetched</code>
Ins	Number of inserted tuples	<code>tup_inserted</code>
Upd	Number of updated tuples	<code>tup_updated</code>
Del	Number of deleted tuples	<code>tup_deleted</code>

Postgres Pro Modules
and Extensions Shipped
as Individual Packages

Column	Description	Field/Calculation
Temp Size	Total amount of data written to temporary files by queries in this database	temp_bytes
Temp Files	Number of temporary files created by queries in this database	temp_files
Size	Database size at the time of the last sample in the report interval	pg_database_size()
Growth	Database growth during the report interval	pg_database_size() increment between interval bounds

The report table “Cluster I/O statistics” provides I/O statistics by object types, backend types and contexts. This table is based on the `pg_stat_io` view of the [Cumulative Statistics System](#), available since Postgres Pro 16. [Table G.2](#) lists columns of this report table. Times are provided in seconds.

Table G.2. Cluster I/O statistics

Column	Description
Object	Target object of an I/O operation
Backend	Type of the backend that performed an I/O operation
Context	The context of an I/O operation
Reads Count	Number of read operations
Reads Bytes	Amount of data read
Reads Time	Time spent in read operations
Writes Count	Number of write operations
Writes Bytes	Amount of data written
Writes Time	Time spent in write operations
Writebacks Count	Number of blocks which the process requested the kernel write out to permanent storage
Writebacks Bytes	Amount of data requested for write out to permanent storage
Writebacks Time	Time spent in writeback operations, including the time spent queueing write-out requests and, potentially, the time spent to write out the dirty data
Extends Count	Number of relation extend operations
Extends Bytes	Amount of space used by extend operations
Extends Time	Time spent in extend operations
Hits	The number of times a desired block was found in a shared buffer
Evictions	Number of times a block has been written out from a shared or local buffer in order to make it available for another use
Reuses	The number of times an existing buffer in a size-limited ring buffer outside of shared buffers was reused as part of an I/O operation in the <code>bulkread</code> , <code>bulkwrite</code> , or <code>vacuum</code> contexts
Fsyncs Count	Number of fsync calls. These are only tracked in context <code>normal</code> .

Postgres Pro Modules
and Extensions Shipped
as Individual Packages

Column	Description
Fsyncs Time	Time spent in fsync operations

The report table “Cluster SLRU statistics” provides access statistics on SLRU (simple least-recently-used) caches. This table is based on the `pg_stat_slru` view of the [Cumulative Statistics System](#). [Table G.3](#) lists columns of this report table. Times are provided in seconds.

Table G.3. Cluster SLRU statistics

Column	Description	Field/Calculation
Name	Name of the SLRU	<code>name</code>
Zeroed	Number of blocks zeroed during initializations	<code>blks_zeroed</code>
Hits	Number of times disk blocks were found already in the SLRU, so that a read was not necessary (this only includes hits in the SLRU, not the operating system's file system cache)	<code>blks_hit</code>
Reads	Number of disk blocks read for this SLRU	<code>blks_read</code>
%Hit	Number of disk block hits for this SLRU as the percentage of $\text{Reads} + \text{Hits}$	$\text{blks\_hit} * 100 / \text{blks\_read} + \text{blks\_hit}$
Writes	Number of disk blocks written for this SLRU	<code>blks_written</code>
Checked	Number of blocks checked for existence for this SLRU	<code>blks_exists</code>
Flushes	Number of flushes of dirty data for this SLRU	<code>flushes</code>
Truncates	Number of truncates for this SLRU	<code>truncates</code>

Table “Session statistics by database” is available in the report for Postgres Pro databases starting with version 14. This table is based on the `pg_stat_database` view of the [Statistics Collector](#). [Table G.4](#) lists columns of this report table. Times are provided in seconds.

Table G.4. Session statistics by database

Column	Description	Field/Calculation
Database	Database name	
Timing Total	Time spent by database sessions in this database during the report interval (note that statistics are only updated when the state of a session changes, so if sessions have been idle for a long time, this idle time won't be included)	<code>session_time</code>
Timing Active	Time spent executing SQL statements in this database during the report interval (this corresponds to the states <code>active</code> and <code>fastpath</code> function call in <code>pg_stat_activity</code>)	<code>active_time</code>

Postgres Pro Modules
and Extensions Shipped
as Individual Packages

Column	Description	Field/Calculation
Timing Idle (T)	Time spent idling while in a transaction in this database during the report interval (this corresponds to the states <code>idle in transaction</code> and <code>idle in transaction (aborted)</code> in <code>pg_stat_activity</code>)	<code>idle_in_transaction_time</code>
Sessions Established	Total number of sessions established to this database during the report interval	<code>sessions</code>
Sessions Abandoned	Number of database sessions to this database that were terminated because connection to the client was lost during the report interval	<code>sessions_abandoned</code>
Sessions Fatal	Number of database sessions to this database that were terminated by fatal errors during the report interval	<code>sessions_fatal</code>
Sessions Killed	Number of database sessions to this database that were terminated by operator intervention during the report interval	<code>sessions_killed</code>

In Postgres Pro Standard databases of versions that include [pgpro_stats](#) version starting with 1.4, workload statistics of vacuum processes are available. The “Database vacuum statistics” report table provides per-database aggregated total vacuum statistics based on the `pgpro_stats_vacuum_tables` view. [Table G.5](#) lists columns of this report table. Times are provided in seconds.

Table G.5. Database vacuum statistics

Column	Description	Field/Calculation
Database	Database name	
Blocks fetched	Total number of database blocks fetched by vacuum operations	<code>total_blks_read</code> + <code>total_blks_hit</code>
%Total	Total number of database blocks fetched (read+hit) by vacuum operations as the percentage of all blocks fetched in the cluster	<code>Blocks fetched * 100 / Cluster fetched</code>
Blocks read	Total number of database blocks read by vacuum operations	<code>total_blks_read</code>
%Total	Total number of database blocks read by vacuum operations as the percentage of all blocks read in the cluster	<code>Blocks read * 100 / Cluster read</code>
VM Frozen	Total number of blocks marked all-frozen in the visibility map	<code>pages_frozen</code>
VM Visible	Total number of blocks marked all-visible in the visibility map	<code>pages_all_visible</code>
Tuples deleted	Total number of dead tuples vacuum operations deleted from tables of this database	<code>tuples_deleted</code>

Postgres Pro Modules
and Extensions Shipped
as Individual Packages

Column	Description	Field/Calculation
Tuples left	Total number of dead tuples vacuum operations left in tables of this database due to their visibility in transactions	dead_tuples
%Eff	Vacuum efficiency in terms of deleted tuples. This is the percentage of tuples deleted from tables of this database in all dead tuples to be deleted from tables of this database.	$\text{tuples\_deleted} * 100 / (\text{tuples\_deleted} + \text{dead\_tuples})$
WAL size	Total amount of WAL bytes generated by vacuum operations performed on tables of this database	wal_bytes
Read I/O time	Time spent reading database blocks by vacuum operations performed on tables of this database	blk_read_time
Write I/O time	Time spent writing database blocks by vacuum operations performed on tables of this database	blk_write_time
%Total	Vacuum I/O time spent as the percentage of whole cluster I/O time	
Total vacuum time	Total time of vacuuming tables of this database	total_time
Delay vacuum time	Time spent sleeping in a vacuum delay point by vacuum operations performed on tables of this database	delay_time
User CPU time	User CPU time of vacuuming tables of this database	user_time
System CPU time	System CPU time of vacuuming tables of this database	system_time
Interrupts	Number of times vacuum operations performed on tables of this database were interrupted on any errors	interrupts

If the [pgpro_stats](#) extension supporting invalidation statistics was available during the report interval, the "Invalidation messages by database" report table provides per-database aggregated total invalidation message statistics. [Table G.6](#) lists columns of this report table.

Table G.6. Invalidation messages by database

Column	Description	Field/Calculation
Database	Database name	
Invalidation messages sent	Total number of invalidation messages sent by backends in this database. Statistics are provided for corresponding message	Fields of pgpro_stats_totals.inval_msgs

Postgres Pro Modules
and Extensions Shipped
as Individual Packages

Column	Description	Field/Calculation
	types of pgpro_stats_inval_msgs	
Cache resets	Total number of shared cache resets	pgpro_stats_totals.cache_resets

If the [pgpro_stats](#) extension was available during the report interval, the “Statement statistics by database” report table provides per-database aggregated total statistics for the `pgpro_stats_statements` view data. [Table G.7](#) lists columns of this report table. Times are provided in seconds.

Table G.7. Statement statistics by database

Column	Description	Field/Calculation
Database	Database name	
Calls	Number of times all statements in the database were executed	calls
Plan Time	Time spent planning all statements in the database	Sum of total_plan_time
Exec Time	Time spent executing all statements in the database	Sum of total_exec_time
Read Time	Time spent reading blocks by all statements in the database	Sum of blk_read_time
Write Time	Time spent writing blocks by all statements in the database	Sum of blk_write_time
Trg Time	Time spent executing trigger functions by all statements in the database	
Shared Fetched	Total number of shared blocks fetched by all statements in the database	Sum of (shared_blks_read + shared_blks_hit)
Local Fetched	Total number of local blocks fetched by all statements in the database	Sum of (local_blks_read + local_blks_hit)
Shared Dirtied	Total number of shared blocks dirtied by all statements in the database	Sum of shared_blks_dirtied
Local Dirtied	Total number of local blocks dirtied by all statements in the database	Sum of local_blks_dirtied
Read Temp	Total number of temp blocks read by all statements in the database	Sum of temp_blks_read
Write Temp	Total number of temp blocks written by all statements in the database	Sum of temp_blks_written
Read Local	Total number of local blocks read by all statements in the database	Sum of local_blks_read
Write Local	Total number of local blocks written by all statements in the database	Sum of local_blks_written

Postgres Pro Modules
and Extensions Shipped
as Individual Packages

Column	Description	Field/Calculation
Statements	Total number of captured statements	
WAL Size	Total amount of WAL generated by all statements in the database	Sum of wal_bytes

The “Statement average min/max timings” report table contains per-database aggregated min/max timing statistics from the one of [pgpro_stats](#) or [pg_stat_statements](#) extensions that was available during the report interval, with the precedence of [pgpro_stats](#). This report is sensitive to the fastest and slowest planning and execution of every statement in a cluster. That is, you can see execution and planning stability in your database. [Table G.8](#) lists columns of this report table.

Table G.8. Statement average min/max timings

Column	Description
Database	Database name
Min average planning time (ms)	The average value of min_plan_time for all statements and all samples included in the report
Max average planning time (ms)	The average value of max_plan_time for all statements and all samples included in the report
Delta% of average planning times	Difference between the mean max_plan_time and mean min_plan_time as the percentage of the mean min_plan_time. The less this difference, the more stable query planning in your database is.
Min average execution time (ms)	The average value of min_exec_time for all statements and all samples included in the report
Max average execution time (ms)	The average value of max_exec_time for all statements and all samples included in the report
Delta% of average execution times	Difference between the mean max_exec_time and mean min_exec_time as the percentage of the mean min_exec_time. The less this difference, the more stable query execution in your database is.
Statements	Total count of captured statements

If the JIT-related statistics was available in the statement statistics extension during the report interval, the “JIT statistics by database” report table provides per-database aggregated total statistics of JIT executions. [Table G.9](#) lists columns of this report table. Times are provided in seconds.

Table G.9. JIT statistics by database

Column	Description	Field/Calculation
Database	Database name	
Calls	Number of times all statements in the database were executed	calls
Plan Time	Time spent planning all statements in the database	Sum of total_plan_time
Exec Time	Time spent executing all statements in the database	Sum of total_exec_time
Generation count	Total number of functions JIT-compiled by the statements	Sum of jit_functions

Postgres Pro Modules
and Extensions Shipped
as Individual Packages

Column	Description	Field/Calculation
Generation time	Total time spent by the statements on generating JIT code	Sum of <code>jit_generation_time</code>
Inlining count	Number of times functions have been inlined	Sum of <code>jit_inlining_count</code>
Inlining time	Total time spent by statements on inlining functions	Sum of <code>jit_inlining_time</code>
Optimization count	Number of times statements have been optimized	Sum of <code>jit_optimization_count</code>
Optimization time	Total time spent by statements on optimizing	Sum of <code>jit_optimization_time</code>
Emission count	Number of times code has been emitted	Sum of <code>jit_emission_count</code>
Emission time	Total time spent by statements on emitting code	Sum of <code>jit_emission_time</code>
Deform count	Number of tuple deform functions JIT-compiled by the statement of the database	
Deform time	Total time spent by the statements of the database on JIT-compiling the tuple deform functions	

The report table “Cluster statistics” provides data from the `pg_stat_bgwriter` view. Table G.10 lists rows of this report table. Times are provided in seconds.

Table G.10. Cluster statistics

Row	Description	Field/Calculation
Scheduled checkpoints	Number of scheduled checkpoints that have been performed	<code>checkpoints_timed</code>
Requested checkpoints	Number of requested checkpoints that have been performed	<code>checkpoints_req</code>
Checkpoint write time (s)	Total amount of time that has been spent in the portion of checkpoint processing where files are written to disk	<code>checkpoint_write_time</code>
Checkpoint sync time (s)	Total amount of time that has been spent in the portion of checkpoint processing where files are synchronized to disk	<code>checkpoint_sync_time</code>
Checkpoint buffers written	Number of buffers written during checkpoints	<code>buffers_checkpoint</code>
Background buffers written	Number of buffers written by the background writer	<code>buffers_clean</code>
Backend buffers written	Number of buffers written directly by a backend. Will not be shown since Postgres Pro 17.	<code>buffers_backend</code>
Backend fsync count	Number of times a backend had to execute its own <code>fsync</code> call (normally the background writer handles those even when the	<code>buffers_backend_fsync</code>

Postgres Pro Modules
and Extensions Shipped
as Individual Packages

Row	Description	Field/Calculation
	backend does its own write). Will not be shown since Postgres Pro 17.	
Bgwriter interrupts (too many buffers)	Number of times the background writer stopped a cleaning scan because it had written too many buffers	maxwritten_clean
Number of buffers allocated	Total number of buffers allocated	buffers_alloc
WAL generated	Total amount of WAL generated	pg_current_wal_lsn() value increment
Start LSN	Log sequence number at the start of a report interval	pg_current_wal_lsn() at the first sample of a report
End LSN	Log sequence number at the end of a report interval	pg_current_wal_lsn() at the last sample of a report
WAL generated by vacuum	Total amount of WAL generated by vacuum	Based on the wal_bytes field of the pgpro_stats_vacuum_databases view.
WAL segments archived	Total number of archived WAL segments	Based on pg_stat_archiver.archived_count
WAL segments archive failed	Total number of WAL segment archiver failures	Based on pg_stat_archiver.failed_count .
Archiver performance	Average archiver process performance per second	Based on the active_time field of the pgpro_stats_archiver view.
Archive command performance	Average archive_command performance per second	Based on the archive_command_time field of the pgpro_stats_archiver view.

Table “WAL statistics” is available in the report for Postgres Pro databases starting with version 14. This table is based on the [pg_stat_wal](#) view of the [Statistics Collector](#). [Table G.11](#) lists columns of this report table. Times are provided in seconds.

Table G.11. WAL statistics

Row	Description	Field/Calculation
WAL generated	Total amount of WAL generated during the report interval	wal_bytes
WAL per second	Average amount of WAL generated per second during the report interval	wal_bytes / report_duration
WAL records	Total number of WAL records generated during the report interval	wal_records
WAL FPI	Total number of WAL full page images generated during the report interval	wal_fpi
WAL buffers full	Number of times WAL data was written to disk because WAL buffers became full during the report interval	wal_buffers_full

Postgres Pro Modules
and Extensions Shipped
as Individual Packages

Row	Description	Field/Calculation
WAL writes	Number of times WAL buffers were written out to disk via <code>XLogWrite</code> request during the report interval	<code>wal_write</code>
WAL writes per second	Average number of times WAL buffers were written out to disk via <code>XLogWrite</code> request per second during the report interval	<code>wal_write / report_duration</code>
WAL sync	Number of times WAL files were synced to disk via <code>issue_xlog_fsync</code> request during the report interval (if <code>fsync</code> is on and <code>wal_sync_method</code> is either <code>fdatasync</code> , <code>fsync</code> or <code>fsync_writethrough</code> , otherwise zero). See Section 28.5 for more information about the internal WAL function <code>issue_xlog_fsync</code> .	<code>wal_sync</code>
WAL syncs per second	Average number of times WAL files were synced to disk via <code>issue_xlog_fsync</code> request per second during the report interval	<code>wal_sync / report_duration</code>
WAL write time	Total amount of time spent writing WAL buffers to disk via <code>XLogWrite</code> request during the report interval (if <code>track_wal_io_timing</code> is enabled, otherwise zero; for more details, see Section 18.9). This includes the sync time when <code>wal_sync_method</code> is either <code>open_datasync</code> or <code>open_sync</code> .	<code>wal_write_time</code>
WAL write duty	WAL write time as the percentage of the report interval duration	<code>wal_write_time * 100 / report_duration</code>
WAL sync time	Total amount of time spent syncing WAL files to disk via <code>issue_xlog_fsync</code> request during the report interval (if <code>track_wal_io_timing</code> is enabled, <code>fsync</code> is on, and <code>wal_sync_method</code> is either <code>fdatasync</code> , <code>fsync</code> or <code>fsync_writethrough</code> , otherwise zero).	<code>wal_sync_time</code>
WAL sync duty	WAL sync time as the percentage of the report interval duration	<code>wal_sync_time * 100 / report_duration</code>

The report table “Tablespace statistics” provides information on the sizes and growth of tablespaces. [Table G.12](#) lists columns of this report table.

Table G.12. Tablespace statistics

Column	Description	Field/Calculation
Tablespace	Tablespace name	<code>pg_tablespace .spcname</code>
Path	Tablespace path	<code>pg_tablespace_location()</code>
Size	Tablespace size at the time of the last sample in the report interval	<code>pg_tablespace_size()</code>
Growth	Tablespace growth during the report interval	<code>pg_tablespace_size()</code> increment between interval bounds

If the [pgpro_stats](#) extension was available during the report interval, the report table “Wait statistics by database” shows the total wait time by wait event type and database. [Table G.13](#) lists columns of this report table.

Table G.13. Wait statistics by database

Column	Description
Database	Database name
Wait event type	Type of event for which the backends were waiting. Asterisk means aggregation of all wait event types in the database.
Waited (s)	Time spent waiting in events of <code>Wait event type</code> , in seconds
%Total	Percentage of wait time spent in the database events of <code>Wait event type</code> in all wait time for the cluster

If the [pgpro_stats](#) extension was available during the report interval, the report table “Top wait events” shows top wait events in the cluster by wait time. [Table G.14](#) lists columns of this report table.

Table G.14. Top wait events

Column	Description
Database	Database name
Wait event type	The type of event for which the backends were waiting
Wait event	Wait event name for which the backends were waiting
Waited	Total wait time spent in <code>Wait event</code> of the database, in seconds
%Total	Percentage of wait time spent in <code>Wait event</code> of the database in all wait time in the cluster

G.1.11.2. Load distribution

This section of a `pgpro_pwr` report is based on the `pgpro_stats_totals` view of the [pgpro_stats](#) extension if it was available during the report interval. Each table in this section provides data for the report interval on load distribution for a certain kind of objects for which aggregated statistics are collected, such as databases, applications, hosts, or users. Each table contains one row for each resource (for example, total time or shared blocks written), where load distribution is shown in graphics, as a stacked bar chart for top objects by load of this resource. If the bar chart area that corresponds to an object is too narrow to include captions, point that area to get a hint with the caption, value and percentage.

The report tables “Load distribution among heavily loaded databases”, “Load distribution among heavily loaded applications”, “Load distribution among heavily loaded hosts” and “Load distribution among heavily loaded users” show load distribution for respective objects. [Table G.15](#) lists rows of these report tables.

Table G.15. Load distribution

Row	Description	Calculation
Total time (sec.)	Total time spent in the planning and execution of statements	<code>total_plan_time + total_exec_time</code>
Executed count	Number of queries executed	<code>queries_executed</code>
I/O time (sec.)	Total time the statements spent reading or writing blocks (if track_io_timing is enabled, otherwise zero)	<code>blk_read_time + blk_write_time</code>
Blocks fetched	Total number of shared block cache hits and shared blocks read by the statements	<code>shared_blks_hit + shared_blks_read</code>
Shared blocks read	Total number of shared blocks read by the statements	<code>shared_blks_read</code>
Shared blocks dirtied	Total number of shared blocks dirtied by the statements	<code>shared_blks_dirtied</code>
Shared blocks written	Total number of shared blocks written by the statements	<code>shared_blks_written</code>
WAL generated	Total amount of WAL generated by the statements	<code>wal_bytes</code>
Temp and Local blocks written	Total number of temporary and local blocks written by the statements	<code>temp_blks_written + local_blks_written</code>
Temp and Local blocks read	Total number of temp and local blocks read by the statements	<code>temp_blks_read + local_blks_read</code>
Invalidation messages sent	Total number of all invalidation messages sent by backends in this database	<code>(pgpro_stats_totals.inval_msgs).all</code>
Cache resets	Total number of shared cache resets	<code>pgpro_stats_totals.cache_resets</code>

G.1.11.3. Session states observed by subsamples

This section of a `pgpro_pwr` report provides information about session states captured by subsamples during the report interval.

Tables of this report section are described below.

The report subsection “Chart with session state” visualizes session states captured by subsamples. It is the timeline chart showing captured session states in backends and transactions. Every state contains a popup with session state attributes. Click on a state to see this state in the table of session states.

The report table “Session state statistics by database” shows the aggregated data on session states. Only session states captured in subsamples are counted. [Table G.16](#) lists columns of this report table.

Table G.16. Session state statistics by database

Column	Description
Database	Database name

Postgres Pro Modules
and Extensions Shipped
as Individual Packages

Column	Description
Summary Active	Overall time of active states captured in subsamples
Summary Idle in xact	Overall time of idle in transaction states captured in subsamples
Summary Idle in xact (A)	Overall time of idle in transaction (aborted) states captured in subsamples
Maximal Active	Time of the longest active state captured in subsamples
Maximal Idle in xact	Time of the longest idle in transaction state captured in subsamples
Maximal Idle in xact (A)	Time of the longest idle in transaction (aborted) state captured in subsamples
Maximal xact age	Maximal transaction age detected in subsamples

The report table “Top 'idle in transaction' session states by duration” shows top `pgpro_pwr.max` longest idle in transaction states that were last observed in the `pg_stat_activity` view for each session. [Table G.17](#) lists columns of this report table.

Table G.17. Top 'idle in transaction' session states by duration

Column	Description	Field/Calculation
Database	Database name	<code>datname</code>
User	User name	<code>username</code>
App	Application name	<code>application_name</code>
Pid	Process ID	<code>pid</code>
Xact start	Transaction start timestamp	<code>xact_start</code>
State change	State change timestamp	<code>state_change</code>
State duration	State duration	<code>clock_timestamp() - state_change</code>

The report table “Top 'active' session states by duration” shows top `pgpro_pwr.max` longest active states that were last observed in the `pg_stat_activity` view for each session. [Table G.18](#) lists columns of this report table.

Table G.18. Top 'active' session states by duration

Column	Description	Field/Calculation
Database	Database name	<code>datname</code>
User	User name	<code>username</code>
App	Application name	<code>application_name</code>
Pid	Process ID	<code>pid</code>
Xact start	Transaction start timestamp	<code>xact_start</code>
State change	State change timestamp	<code>state_change</code>
State duration	State duration	<code>clock_timestamp() - state_change</code>

The report table “Top states by transaction age” shows top session states by transaction age that were last observed in the `pg_stat_activity` view for each session. [Table G.19](#) lists columns of this report table.

Table G.19. Top states by transaction age

Column	Description	Field/Calculation
Database	Database name	datname
User	User name	username
App	Application name	application_name
Pid	Process ID	pid
Xact start	Transaction start timestamp	xact_start
Xact duration	Transaction duration	clock_timestamp() - xact_start
Age	Transaction age	age(backend_xmin)
State	Session state at the maximum age detected	
State change	State change timestamp	state_change
State duration	State duration	clock_timestamp() - state_change

The report table “Top states by transaction duration” shows top longest session states that were last observed in the [pg_stat_activity](#) view for each session. [Table G.20](#) lists columns of this report table.

Table G.20. Top states by transaction duration

Column	Description	Field/Calculation
Database	Database name	datname
User	User name	username
App	Application name	application_name
Pid	Process ID	pid
Xact start	Transaction start timestamp	xact_start
Xact duration	Transaction duration	clock_timestamp() - xact_start
Age	Transaction age	age(backend_xmin)
State	Session state at the maximum age detected	
State change	State change timestamp	state_change
State duration	State duration	clock_timestamp() - state_change

G.1.11.4. SQL query statistics

This section of a pgpro_pwr report provides data for the report interval on top statements by several important statistics. The data is mainly captured from views of the one of [pgpro_stats](#) and [pg_stat_statements](#) extensions that was available during the report interval, with the precedence of pgpro_stats. Each statement can be highlighted in all SQL-related sections with a single mouse click on it. This click will also show a query text preview just under the query statistics row. The query text preview can be hidden with a second click on a query.

Tables of this report section are described below.

The report table “Top SQL by elapsed time” shows top statements by the sum of `total_plan_time` and `total_exec_time` fields of the `pgpro_stats_statements` or `pg_stat_statements` view. [Table G.21](#) lists columns of this report table. Times are provided in seconds.

Table G.21. Top SQL by elapsed time

Column	Description	Field/Calculation
Query ID	Hex representation of <code>queryid</code> . The hash of the query ID, database ID and user ID is in square brackets. The (N) mark will appear here for nested statements (such as statements invoked within top-level statements).	
Plan ID	Internal hash code, computed from the tree of the statement plan	<code>planid</code>
Database	Database name for the statement	Derived from <code>dbid</code>
User	Name of the user executing the statement	Derived from <code>userid</code>
%Total	Percentage of elapsed time of this statement plan in the total elapsed time of all statements in the cluster	
Elapsed Time (s)	Total time spent in planning and execution of the statement plan	<code>total_plan_time</code> + <code>total_exec_time</code>
Plan Time (s)	Total time spent in planning of the statement	<code>total_plan_time</code>
Exec Time (s)	Total time spent in execution of the statement plan	<code>total_exec_time</code>
JIT Time (s)	Total time spent by JIT executing this statement plan, in seconds	<code>jit_generation_time</code> + <code>jit_inlining_time</code> + <code>jit_optimization_time</code> + <code>jit_emission_time</code>
Read I/O time (s)	Total time the statement spent reading blocks	<code>blk_read_time</code>
Write I/O time (s)	Total time the statement spent writing blocks	<code>blk_write_time</code>
Usr CPU time (s)	Time spent on CPU in the user space, in seconds	<code>rusage.user_time</code>
Sys CPU time (s)	Time spent on CPU in the system space, in seconds	<code>rusage.system_time</code>
Plans	Number of times the statement was planned	<code>plans</code>
Executions	Number of executions of the statement plan	<code>calls</code>
%Cvr	Coverage: duration of statement statistics collection as the percentage of the report duration	

The report table “Top SQL by planning time” shows top statements by the value of the `total_plan_time` field of the `pgpro_stats_statements` or `pg_stat_statements` view. [Table G.22](#) lists columns of this report table.

Table G.22. Top SQL by planning time

Column	Description	Field/Calculation
Query ID	Hex representation of <code>queryid</code> . The hash of the query ID, database ID and user ID is in square brackets. The (N) mark will appear here for nested statements (such as statements invoked within top-level statements).	
Plan ID	Internal hash code, computed from the tree of the statement plan	<code>planid</code>
Database	Database name for the statement	Derived from <code>dbid</code>
User	Name of the user executing the statement	Derived from <code>userid</code>
Plan elapsed(s)	Total time spent in planning of the statement, in seconds	<code>total_plan_time</code>
%Elapsed	Percentage of <code>total_plan_time</code> in the sum of <code>total_plan_time</code> and <code>total_exec_time</code> of this statement plan	
Mean plan time	Mean time spent planning the statement, in milliseconds	<code>mean_plan_time</code>
Min plan time	Minimum time spent planning the statement, in milliseconds	<code>min_plan_time</code>
Max plan time	Maximum time spent planning the statement, in milliseconds	<code>max_plan_time</code>
StdErr plan time	Population standard deviation of time spent planning the statement, in milliseconds	<code>stddev_plan_time</code>
Plans	Number of times the statement was planned	<code>plans</code>
Executions	Number of executions of the statement plan	<code>calls</code>
%Cvr	Coverage: duration of statement statistics collection as the percentage of the report duration	

The report table “Top SQL by execution time” shows top statements by the value of the `total_time` field of the `pgpro_stats_statements` or `pg_stat_statements` view. [Table G.23](#) lists columns of this report table.

Table G.23. Top SQL by execution time

Column	Description	Field/Calculation
Query ID	Hex representation of <code>queryid</code> . The hash of the query ID, database ID and user ID is in square brackets. The (N) mark will appear here for nested statements (such as statements invoked within top-level statements).	

Postgres Pro Modules
and Extensions Shipped
as Individual Packages

Column	Description	Field/Calculation
Plan ID	Internal hash code, computed from the tree of the statement plan	planid
Database	Database name for the statement	Derived from dbid
User	Name of the user executing the statement	Derived from userid
Exec (s)	Total time spent executing the statement plan, in seconds	total_exec_time
%Elapsed	Percentage of total_exec_time of this statement plan in this statement elapsed time	
%Total	Percentage of total_exec_time of this statement plan in the total elapsed time of all statements in the cluster	
JIT Time (s)	Total time spent by JIT executing this statement plan, in seconds	jit_generation_time + jit_inlining_time + jit_optimization_time + jit_emission_time
Read I/O time (s)	Total time spent in reading pages while executing the statement plan, in seconds	blk_read_time
Write I/O time (s)	Total time spent in writing pages while executing the statement plan, in seconds	blk_write_time
Usr CPU time (s)	Time spent on CPU in the user space, in seconds	rusage.user_time
Sys CPU time (s)	Time spent on CPU in the system space, in seconds	rusage.system_time
Rows	Number of rows retrieved or affected by execution of the statement plan	rows
Mean execution time	Mean time spent executing the statement plan, in milliseconds	mean_exec_time
Min execution time	Minimum time spent executing the statement plan, in milliseconds	min_exec_time
Max execution time	Maximum time spent executing the statement plan, in milliseconds	max_exec_time
StdErr execution time	Population standard deviation of time spent executing the statement plan, in milliseconds	stddev_exec_time
Executions	Number of executions of this statement plan	calls
%Cvr	Coverage: duration of statement statistics collection as the percentage of the report duration	

Postgres Pro Modules
and Extensions Shipped
as Individual Packages

The report table “Top SQL by mean execution time” shows top `pgpro_pwr.max` statements by the value of the `mean_time` or `mean_exec_time` field of the `pgpro_stats_statements` or `pg_stat_statements` view. [Table G.24](#) lists columns of this report table.

Table G.24. Top SQL by mean execution time

Column	Description	Field/Calculation
Query ID	Hex representation of <code>queryid</code> . The hash of the query ID, database ID and user ID is in square brackets. The (N) mark will appear here for nested statements (such as statements invoked within top-level statements).	
Database	Database name for the statement	Derived from <code>dbid</code>
User	Name of the user executing the statement	Derived from <code>userid</code>
Mean execution time (ms)	Mean time spent executing the statement, in milliseconds	<code>mean_exec_time</code>
Min execution time (ms)	Minimum time spent executing the statement, in milliseconds	<code>min_exec_time</code>
Max execution time (ms)	Maximum time spent executing the statement, in milliseconds	<code>max_exec_time</code>
StdErr execution time	Population standard deviation of time spent executing the statement, in milliseconds	<code>stddev_exec_time (ms)</code>
Exec (s)	Time spent executing this statement, in seconds	<code>total_exec_time</code>
%Elapsed	Execution time of this statement as the percentage of the statement elapsed time	
%Total	Execution time of this statement as the percentage of the total elapsed time of all statements in the cluster	
JIT time (s)	Total time spent by JIT executing this statement, in seconds	<code>jit_generation_time + jit_inlining_time + jit_optimization_time + jit_emission_time</code>
Read I/O time (s)	Time spent reading blocks, in seconds	<code>blk_read_time</code>
Write I/O time (s)	Time spent writing blocks, in seconds	<code>blk_write_time</code>
Rows	Number of rows retrieved or affected by the statement	<code>rows</code>
Executions	Number of times this statement was executed	<code>calls</code>
%Cvr	Coverage: duration of statement statistics collection as the percentage of the report duration	

The report table “Top SQL by executions” shows top statements by the value of the `calls` field of the `pgpro_stats_statements` or `pg_stat_statements` view. [Table G.25](#) lists columns of this report table.

Table G.25. Top SQL by executions

Column	Description	Field/Calculation
Query ID	Hex representation of <code>queryid</code> . The hash of the query ID, database ID and user ID is in square brackets. The (N) mark will appear here for nested statements (such as statements invoked within top-level statements).	
Plan ID	Internal hash code, computed from the tree of the statement plan	<code>planid</code>
Database	Database name for the statement	Derived from <code>dbid</code>
User	Name of the user executing the statement	Derived from <code>userid</code>
Executions	Number of executions of the statement plan	<code>calls</code>
%Total	Percentage of <code>calls</code> of this statement plan in the total <code>calls</code> of all statements in the cluster	
Rows	Number of rows retrieved or affected by execution of the statement plan	<code>rows</code>
Mean (ms)	Mean time spent executing the statement plan, in milliseconds	<code>mean_exec_time</code>
Min (ms)	Minimum time spent executing the statement plan, in milliseconds	<code>min_exec_time</code>
Max (ms)	Maximum time spent executing the statement plan, in milliseconds	<code>max_exec_time</code>
StdErr (ms)	Population standard deviation of time spent executing the statement plan, in milliseconds	<code>stddev_time</code>
Elapsed(s)	Total time spent executing the statement plan, in seconds	<code>total_exec_time</code>
%Cvr	Coverage: duration of statement statistics collection as the percentage of the report duration	

The report table “Top SQL by I/O wait time” shows top statements by read and write time, i.e., sum of values of `blk_read_time` and `blk_write_time` fields of the `pgpro_stats_statements` or `pg_stat_statements` view. [Table G.26](#) lists columns of this report table. Times are provided in seconds.

Table G.26. Top SQL by I/O wait time

Column	Description	Field/Calculation
Query ID	Hex representation of <code>queryid</code> . The hash of the query ID, database ID and user ID is in square brackets. The (N) mark will appear here for nested statements	

Postgres Pro Modules
and Extensions Shipped
as Individual Packages

	(such as statements invoked within top-level statements).	
Plan ID	Internal hash code, computed from the tree of the statement plan	planid
Database	Database name for the statement	Derived from dbid
User	Name of the user executing the statement	Derived from userid
IO(s)	Total time spent in reading and writing while executing this statement plan, i.e., I/O time	blk_read_time + blk_write_time
R(s)	Total time spent in reading while executing this statement plan	blk_read_time
W(s)	Total time spent in writing while executing this statement plan	blk_write_time
%Total	Percentage of I/O time of this statement plan in the total I/O time of all statements in the cluster	
Shr Reads	Total number of shared blocks read while executing the statement plan	shared_blks_read
Loc Reads	Total number of local blocks read while executing the statement plan	local_blks_read
Tmp Reads	Total number of temp blocks read while executing the statement plan	temp_blks_read
Shr Writes	Total number of shared blocks written while executing the statement plan	shared_blks_written
Loc Writes	Total number of local blocks written while executing the statement plan	local_blks_written
Tmp Writes	Total number of temp blocks written while executing the statement plan	temp_blks_written
Elapsed(s)	Total time spent in execution of the statement plan	total_plan_time + total_exec_time
Executions	Number of executions of the statement plan	calls
%Cvr	Coverage: duration of statement statistics collection as the percentage of the report duration	

The report table “Top SQL by shared blocks fetched” shows top statements by the number of read and hit blocks, which helps to detect the most data-intensive statements. [Table G.27](#) lists columns of this report table.

Table G.27. Top SQL by shared blocks fetched

Column	Description	Field/Calculation
Query ID	Hex representation of <code>queryid</code> . The hash of the query ID, database ID and user ID is in square brackets. The (N) mark will appear here for nested statements (such as statements invoked within top-level statements).	
Plan ID	Internal hash code, computed from the tree of the statement plan	<code>planid</code>
Database	Database name for the statement	Derived from <code>dbid</code>
User	Name of the user executing the statement	Derived from <code>userid</code>
Blks fetched	Number of blocks retrieved while executing the statement plan	<code>shared_blks_hit</code> + <code>shared_blks_read</code>
%Total	Percentage of blocks fetched while executing the statement plan in all blocks fetched for all statements in the cluster	
Hits(%)	Percentage of blocks got from buffers in all blocks got	
Elapsed(s)	Total time spent in execution of the statement plan, in seconds	<code>total_plan_time</code> + <code>total_exec_time</code>
Rows	Number of rows retrieved or affected by execution of the statement plan	<code>rows</code>
Executions	Number of executions of the statement plan	<code>calls</code>
%Cvr	Coverage: duration of statement statistics collection as the percentage of the report duration	

The report table “Top SQL by shared blocks read” shows top statements by the number of shared reads, which helps to detect the most read-intensive statements. [Table G.28](#) lists columns of this report table.

Table G.28. Top SQL by shared blocks read

Column	Description	Field/Calculation
Query ID	Hex representation of <code>queryid</code> . The hash of the query ID, database ID and user ID is in square brackets. The (N) mark will appear here for nested statements (such as statements invoked within top-level statements).	
Plan ID	Internal hash code, computed from the tree of the statement plan	<code>planid</code>
Database	Database name for the statement	Derived from <code>dbid</code>

Postgres Pro Modules
and Extensions Shipped
as Individual Packages

Column	Description	Field/Calculation
User	Name of the user executing the statement	Derived from <code>userid</code>
Reads	Number of shared blocks read while executing this statement plan	<code>shared_blks_read</code>
%Total	Percentage of shared reads for this statement plan in all shared reads of all statements in the cluster	
Hits (%)	Percentage of blocks got from buffers in all blocks got while executing this statement plan	
Elapsed (s)	Total time spent in execution of the statement plan, in seconds	<code>total_plan_time</code> + <code>total_exec_time</code>
Rows	Number of rows retrieved or affected by execution of the statement plan	<code>rows</code>
Executions	Number of executions of the statement plan	<code>calls</code>
%Cvr	Coverage: duration of statement statistics collection as the percentage of the report duration	

The report table “Top SQL by shared blocks dirtied” shows top statements by the number of shared dirtied buffers, which helps to detect statements that do most data changes in the cluster. [Table G.29](#) lists columns of this report table.

Table G.29. Top SQL by shared blocks dirtied

Column	Description	Field/Calculation
Query ID	Hex representation of <code>queryid</code> . The hash of the query ID, database ID and user ID is in square brackets. The (N) mark will appear here for nested statements (such as statements invoked within top-level statements).	
Plan ID	Internal hash code, computed from the tree of the statement plan	<code>planid</code>
Database	Database name for the statement	Derived from <code>dbid</code>
User	Name of the user executing the statement	Derived from <code>userid</code>
Dirtied	Number of shared buffers dirtied while executing this statement plan	<code>shared_blks_dirtied</code>
%Total	Percentage of dirtied shared buffers for this statement plan in all dirtied shared buffers of all statements in the cluster	

Postgres Pro Modules
and Extensions Shipped

Column	Description	Field/Calculation
Hits (%)	Percentage of blocks got from buffers in all blocks got while executing this statement plan	
Elapsed (s)	Total time spent in execution of the statement plan, in seconds	<code>total_plan_time</code> + <code>total_exec_time</code>
Rows	Number of rows retrieved or affected by execution of the statement plan	<code>rows</code>
Executions	Number of executions of the statement plan	<code>calls</code>
%Cvr	Coverage: duration of statement statistics collection as the percentage of the report duration	

The report table “Top SQL by WAL size” shows top statements by the amount of WAL generated. [Table G.31](#) lists columns of this report table.

Table G.31. Top SQL by WAL size

Column	Description	Field/Calculation
Query ID	Hex representation of <code>queryid</code> . The hash of the query ID, database ID and user ID is in square brackets. The (N) mark will appear here for nested statements (such as statements invoked within top-level statements).	
Plan ID	Internal hash code, computed from the tree of the statement plan	<code>planid</code>
Database	Database name for the statement	Derived from <code>dbid</code>
User	Name of the user executing the statement	Derived from <code>userid</code>
WAL	Total amount of WAL bytes generated by the statement plan	<code>wal_bytes</code>
%Total	Percentage of WAL bytes generated by the statement plan in total WAL generated in the cluster	
Dirtied	Number of shared buffers dirtied while executing this statement plan	<code>shared_blks_dirtied</code>
WAL FPI	Total number of WAL full page images generated by the statement plan	<code>wal_fpi</code>
WAL records	Total number of WAL records generated by the statement plan	<code>wal_records</code>
%Cvr	Coverage: duration of statement statistics collection as the percentage of the report duration	

Postgres Pro Modules
and Extensions Shipped
as Individual Packages

The report table “Top SQL by temp usage” shows top statements by temporary I/O, which is calculated as the sum of `temp_blks_read`, `temp_blks_written`, `local_blks_read` and `local_blks_written` fields. Table G.32 lists columns of this report table.

Table G.32. Top SQL by temp usage

Column	Description	Field/Calculation
Query ID	Hex representation of <code>queryid</code> . The hash of the query ID, database ID and user ID is in square brackets. The (N) mark will appear here for nested statements (such as statements invoked within top-level statements).	
Plan ID	Internal hash code, computed from the tree of the statement plan	<code>planid</code>
Database	Database name for the statement	Derived from <code>dbid</code>
User	Name of the user executing the statement	Derived from <code>userid</code>
Local fetched	Number of local blocks retrieved	<code>local_blks_hit</code> + <code>local_blks_read</code>
Hits(%)	Percentage of local blocks got from buffers in all local blocks got	
Write Local (blk)	Number of blocks written by this statement plan that are used in temporary tables	<code>local_blks_written</code>
Write Local %Total	Percentage of <code>local_blks_written</code> of this statement plan in the total of <code>local_blks_written</code> for all statements in the cluster	
Read Local (blk)	Number of blocks read by this statement plan that are used in temporary tables	<code>local_blks_read</code>
Read Local %Total	Percentage of <code>local_blks_read</code> of this statement plan in the total of <code>local_blks_read</code> for all statements in the cluster	
Write Temp (blk)	Number of temp blocks written by this statement plan	<code>temp_blks_written</code>
Write Temp %Total	Percentage of <code>temp_blks_written</code> of this statement plan in the total of <code>temp_blks_written</code> for all statements in the cluster	
Read Temp (blk)	Number of temp blocks read by this statement plan	<code>temp_blks_read</code>
Read Temp %Total	Percentage of <code>temp_blks_read</code> of this statement plan in the to-

as Individual Packages

Column	Description	Field/Calculation
	total of temp_blks_read for all statements in the cluster	
Elapsed(s)	Total time spent in execution of the statement plan, in seconds	total_plan_time + total_exec_time
Rows	Number of rows retrieved or affected by execution of the statement plan	rows
Executions	Number of executions of the statement plan	calls
%Cvr	Coverage: duration of statement statistics collection as the percentage of the report duration	

The report table “Top SQL by invalidation messages sent” shows top statements by the number of invalidation messages sent. [Table G.33](#) lists columns of this report table.

Table G.33. Top SQL by invalidation messages sent

Column	Description	Field/Calculation
Query ID	Hex representation of queryid. The hash of the query ID, database ID and user ID is in square brackets. The (N) mark will appear here for nested statements (such as statements invoked within top-level statements).	queryid
Plan ID	Internal hash code, computed from the tree of the statement plan	planid
Database	Database name for the statement	Derived from dbid
User	Name of the user executing the statement	Derived from userid
Invalidation messages sent	Total number of invalidation messages sent by backends executing this statement. Statistics are provided for corresponding message types of pgpro_stats_inval_msgs	fields of pgpro_stats_statements.inval_msgs

G.1.11.4.1. rusage statistics

This section is included in the report only if the [pgpro_stats](#) or pg_stat_kcache extension was available during the report interval.

The report table “Top SQL by system and user time” shows top statements by the sum of user_time and system_time fields of pg_stat_kcache or of the pgpro_stats_totals view. [Table G.34](#) lists columns of this report table.

Table G.34. Top SQL by system and user time

Column	Description	Field/Calculation
Query ID	Hex representation of queryid. The hash of the query ID, database ID and user ID is in square	

Postgres Pro Modules
and Extensions Shipped
as Individual Packages

Column	Description	Field/Calculation
	brackets. The (N) mark will appear here for nested statements (such as statements invoked within top-level statements).	
Plan ID	Internal hash code, computed from the tree of the statement plan	planid
Database	Database name for the statement	Derived from dbid
User	Name of the user executing the statement	Derived from userid
Plan User (s)	User CPU time elapsed during planning, in seconds	plan_user_time
Exec User (s)	User CPU time elapsed during execution, in seconds	exec_user_time
User %Total	Percentage of <code>plan_user_time + exec_user_time</code> in the total user CPU time for all statements	
Plan System (s)	System CPU time elapsed during planning, in seconds	plan_system_time
Exec System (s)	System CPU time elapsed during execution, in seconds	exec_system_time
System %Total	Percentage of <code>plan_system_time + exec_system_time</code> in the total system CPU time for all statements	

The report table “Top SQL by reads/writes done by filesystem layer” shows top statements by the sum of reads and writes fields of `pg_stat_kcache`. [Table G.35](#) lists columns of this report table.

Table G.35. Top SQL by reads/writes done by filesystem layer

Column	Description	Field/Calculation
Query ID	Hex representation of <code>queryid</code> . The hash of the query ID, database ID and user ID is in square brackets. The (N) mark will appear here for nested statements (such as statements invoked within top-level statements).	
Plan ID	Internal hash code, computed from the tree of the statement plan	planid
Database	Database name for the statement	Derived from dbid
User	Name of the user executing the statement	Derived from userid
Plan Read Bytes	Bytes read during planning	plan_reads
Exec Read Bytes	Bytes read during execution	exec_reads
Read Bytes %Total	Percentage of <code>plan_reads + exec_reads</code> in the total number of bytes read by the filesystem layer for all statements	

Postgres Pro Modules
and Extensions Shipped
as Individual Packages

Column	Description	Field/Calculation
Plan Writes	Bytes written during planning	plan_writes
Exec Writes	Bytes written during execution	exec_writes
Write %Total	Percentage of plan_writes + exec_writes in the total number of bytes written by the filesystem layer for all statements	

G.1.11.5. SQL query wait statistics

If the [pgpro_stats](#) extension was available during the report interval, this section of the report will contain a table that is split into sections, each showing top statements by overall wait time or by wait time for a certain [wait event type](#). Table sections related to specific wait events follow in the descending order of the total wait time in wait events of this type. [Table G.36](#) lists columns of this report table. Times are provided in seconds.

Table G.36. SQL query wait statistics

Column	Description	Field/Calculation
Query ID	Hex representation of queryid. The hash of the query ID, database ID and user ID is in square brackets. The (N) mark will appear here for nested statements (such as statements invoked within top-level statements).	
Plan ID	Hash of the statement plan	planid
Database	Database name for the statement	Derived from dbid
User	Name of the user executing the statement	Derived from userid
Waited	Total wait time for all wait events of this statement plan	
%Total	Percentage of the total wait time of this statement plan in all the wait time in the cluster	
Details	Waits of this statement plan by wait types	

If the JIT-related statistics was available in the statement statistics extension during the report interval, the report table “Top SQL by JIT elapsed time” shows top statements by the sum of jit_*_time fields of the pgpro_stats_statements or pg_stat_statements view. [Table G.37](#) lists columns of this report table. Times are provided in seconds.

Table G.37. Top SQL by JIT elapsed time

Column	Description	Field/Calculation
Query ID	Hex representation of queryid. The hash of the query ID, database ID and user ID is in square brackets. The (N) mark will appear here for nested statements (such as statements invoked within top-level statements).	

Postgres Pro Modules
and Extensions Shipped
as Individual Packages

Column	Description	Field/Calculation
Plan ID	Internal hash code, computed from the tree of the statement plan	planid
Database	Database name for the statement	Derived from dbid
User	Name of the user executing the statement	Derived from userid
JIT Time (s)	Total time spent by JIT executing this statement plan	jit_generation_time + jit_inlining_time + jit_optimization_time + jit_emission_time
Generation count	Total number of functions JIT-compiled by this statement	Sum of jit_functions
Generation time	Total time spent by this statement on generating JIT code	Sum of jit_generation_time
Inlining count	Number of times functions have been inlined	Sum of jit_inlining_count
Inlining time	Total time spent by this statement on inlining functions	Sum of jit_inlining_time
Optimization count	Number of times this statement has been optimized	Sum of jit_optimization_count
Optimization time	Total time spent by this statement on optimizing	Sum of jit_optimization_time
Emission count	Number of times code has been emitted	Sum of jit_emission_count
Emission time	Total time spent by this statement on emitting code	Sum of jit_emission_time
Deform count	Number of tuple deform functions JIT-compiled by the statement	
Deform time	Total time spent by the statement on JIT-compiling the tuple deform	
Plan Time (s)	Total time spent in planning of the statement	total_plan_time
Exec Time (s)	Total time spent in execution of the statement plan	total_exec_time
Read I/O time (s)	Total time the statement spent reading blocks	blk_read_time
Write I/O time (s)	Total time the statement spent writing blocks	blk_write_time
%Cvr	Coverage: duration of statement statistics collection as the percentage of the report duration	

G.1.11.6. Complete list of SQL texts

The “Complete list of SQL texts” section of the report contains a table that provides query and plan texts for all statements mentioned in the report. Use an appropriate Query ID/Plan ID link in any statistics table to see the corresponding query/plan text. [Table G.38](#) lists columns of this report table.

Table G.38. Complete list of SQL texts

Column	Description
ID	Hex representation of the query or plan identifier
Query/Plan Text	Text of the query or statement plan

G.1.11.7. Schema object statistics

Tables in this section of the report show top database objects by statistics from the Postgres Pro's [Statistics Collector](#) views. Report tables that contain data for tables and indexes provide a preview of storage parameters. You can click on a row to see storage parameters of the object right under the row.

The report table “Top tables by estimated sequentially scanned volume” shows top tables by estimated volume read by sequential scans. This can help you find database tables that possibly lack some index. When there are no relation sizes collected with `pg_relation_size()`, relation-size estimates are based on the `pg_class.relpages` field. Since such values are less accurate, they are shown in square brackets. The data is based on the `pg_stat_all_tables` view. [Table G.39](#) lists columns of this report table.

Table G.39. Top tables by estimated sequentially scanned volume

Column	Description	Field/Calculation
DB	Database name for the table	
Tablespace	Name of the tablespace where the table is located	
Schema	Schema name for the table	
Table	Table name	
~SeqBytes	Estimated volume read by sequential scans	Sum of (<code>pg_relation_size()</code> * <code>seq_scan</code>)
SeqScan	Number of sequential scans performed on the table	<code>seq_scan</code>
IxScan	Number of index scans initiated on the table	<code>idx_scan</code>
IxFet	Number of live rows fetched by index scans	<code>idx_tup_fetch</code>
Ins	Number of rows inserted	<code>n_tup_ins</code>
Upd	Number of rows updated	<code>n_tup_upd</code>
Del	Number of rows deleted	<code>n_tup_del</code>
Upd (HOT)	Number of rows HOT updated	<code>n_tup_hot_upd</code>

In the report table “Top tables by blocks fetched”, blocks fetched include blocks being processed from disk (read) and from shared buffers (hit). This report table shows top database tables by the sum of blocks fetched for the table's heap, indexes, TOAST table (if any) and TOAST table index (if any). This can help you focus on tables with excessive processing of blocks. The data is based on the `pg_statio_all_tables` view. [Table G.40](#) lists columns of this report table.

Table G.40. Top tables by blocks fetched

Column	Description	Field/Calculation
DB	Database name for the table	
Tablespace	Name of the tablespace where the table is located	
Schema	Schema name for the table	

Postgres Pro Modules
and Extensions Shipped
as Individual Packages

Column	Description	Field/Calculation
Table	Table name	
Heap Blks	Number of blocks fetched for the table's heap	heap_blks_read + heap_blks_hit
Heap Blks %Total	Percentage of blocks fetched for the table's heap in all blocks fetched in the cluster	
Ix Blks	Number of blocks fetched for table's indexes	idx_blks_read + idx_blks_hit
Ix Blks %Total	Percentage of blocks fetched for table's indexes in all blocks fetched in the cluster	
TOAST Blks	Number of blocks fetched for the table's TOAST table	toast_blks_read + toast_blks_hit
TOAST Blks %Total	Percentage of blocks fetched for the table's TOAST table in all blocks fetched in the cluster	
TOAST-Ix Blks	Number of blocks fetched for the table's TOAST index	tidx_blks_read + tidx_blks_hit
TOAST-Ix Blks %Total	Percentage of blocks fetched for the table's TOAST index in all blocks fetched in the cluster	

The report table “Top tables by blocks read” shows top database tables by the number of blocks read for the table's heap, indexes, TOAST table (if any) and TOAST table index (if any). This can help you focus on tables with excessive block readings. The data is based on the [pg_statio_all_tables](#) view. [Table G.41](#) lists columns of this report table.

Table G.41. Top tables by blocks read

Column	Description	Field/Calculation
DB	Database name for the table	
Tablespace	Name of the tablespace where the table is located	
Schema	Schema name for the table	
Table	Table name	
Heap Blks	Number of blocks read for the table's heap	heap_blks_read
Heap Blks %Total	Percentage of blocks read from the table's heap in all blocks read in the cluster	
Ix Blks	Number of blocks read from table's indexes	idx_blks_read
Ix Blks %Total	Percentage of blocks read from table's indexes in all blocks read in the cluster	
TOAST Blks	Number of blocks read from the table's TOAST table	toast_blks_read
TOAST Blks %Total	Percentage of blocks read from the table's TOAST table in all blocks read in the cluster	

Postgres Pro Modules
and Extensions Shipped
as Individual Packages

Column	Description	Field/Calculation
TOAST-Ix Blks	Number of blocks read from the table's TOAST index	tidx_blks_read
TOAST-Ix Blks %Total	Percentage of blocks read from the table's TOAST index in all blocks read in the cluster	
Hit (%)	Percentage of table, index, TOAST and TOAST index blocks got from buffers for this table in all blocks got for this table from either file system or buffers	

The report table “Top DML tables” shows top tables by the number of DML-affected rows, i.e., by the sum of `n_tup_ins`, `n_tup_upd` and `n_tup_del` (including TOAST tables). The data is based on the `pg_stat_all_tables` view. Table G.42 lists columns of this report table.

Table G.42. Top DML tables

Column	Description	Field/Calculation
DB	Database name for the table	
Tablespace	Name of the tablespace where the table is located	
Schema	Schema name for the table	
Table	Table name	
Ins	Number of rows inserted	<code>n_tup_ins</code>
Upd	Number of rows updated, including HOT	<code>n_tup_upd</code>
Del	Number of rows deleted	<code>n_tup_del</code>
Upd (HOT)	Number of rows HOT updated	<code>n_tup_hot_upd</code>
SeqScan	Number of sequential scans performed on the table	<code>seq_scan</code>
SeqFet	Number of live rows fetched by sequential scans	<code>seq_tup_read</code>
IxScan	Number of index scans initiated on this table	<code>idx_scan</code>
IxFet	Number of live rows fetched by index scans	<code>idx_tup_fetch</code>

The report table “Top tables by updated/deleted tuples” shows top tables by tuples modified by UPDATE/DELETE operations, i.e., by the sum of `n_tup_upd` and `n_tup_del` (including TOAST tables). The data is based on the `pg_stat_all_tables` view. Table G.43 lists columns of this report table.

Table G.43. Top tables by updated/deleted tuples

Column	Description	Field/Calculation
DB	Database name for the table	
Tablespace	Name of the tablespace where the table is located	
Schema	Schema name for the table	
Table	Table name	
Upd	Number of rows updated, including HOT	<code>n_tup_upd</code>

Postgres Pro Modules
and Extensions Shipped
as Individual Packages

Column	Description	Field/Calculation
Upd (HOT)	Number of rows HOT updated	n_tup_hot_upd
Del	Number of rows deleted	n_tup_del
Vacuum	Number of times this table has been manually vacuumed (not counting <code>VACUUM FULL</code>)	vacuum_count
AutoVacuum	Number of times this table has been vacuumed by the autovacuum daemon	autovacuum_count
Analyze	Number of times this table was manually analyzed	analyze_count
AutoAnalyze	Number of times this table was analyzed by the autovacuum daemon	autoanalyze_count

The report table “Top tables by removed all-visible marks” shows top tables by the number of times that the all-visible mark was removed from the visibility map by any backend. This report section is only shown when corresponding statistics are available. [Table G.44](#) lists columns of this report table.

Table G.44. Top tables by removed all-visible marks

Column	Description	Field/Calculation
DB	Database name for the table	
Tablespace	Name of the tablespace where the table is located	
Schema	Schema name for the table	
Table	Table name	
All-Visible marks cleared	Number of times that the all-visible mark was removed from the relation visibility map	rev_all_visible_pages
All-Visible marks set	Number of times that the all-visible mark was set in the relation visibility map	pages_all_visible
All-Visible marks %Set	Percentage of the number of times that the all-visible mark was set in the number of times that it was set or removed	$\text{pages\_all\_visible} * 100\% / (\text{rev\_all\_visible\_pages} + \text{pages\_all\_visible})$
Vacuum	Number of times this table has been manually vacuumed (not counting <code>VACUUM FULL</code>)	vacuum_count
AutoVacuum	Number of times this table has been vacuumed by the autovacuum daemon	autovacuum_count

The report table “Top tables by removed all-frozen marks” shows top tables by the number of times that the all-frozen mark was removed from the visibility map by any backend. This report section is only shown when corresponding statistics are available. [Table G.45](#) lists columns of this report table.

Table G.45. Top tables by removed all-frozen marks

Column	Description	Field/Calculation
DB	Database name for the table	

Postgres Pro Modules
and Extensions Shipped
as Individual Packages

Column	Description	Field/Calculation
Tablespace	Name of the tablespace where the table is located	
Schema	Schema name for the table	
Table	Table name	
All-Frozen marks cleared	Number of times that the all-frozen mark was removed from the relation visibility map	rev_all_frozen_pages
All-Frozen marks set	Number of times that the all-frozen mark was set in the relation visibility map	pages_frozen
All-Frozen marks %Set	Percentage of the number of times that the all-frozen mark was set in the number of times that it was set or removed	$\text{pages\_frozen} * 100\% / (\text{rev\_all\_frozen\_pages} + \text{pages\_frozen})$
Vacuum	Number of times this table has been manually vacuumed (not counting VACUUM FULL)	vacuum_count
AutoVacuum	Number of times this table has been vacuumed by the autovacuum daemon	autovacuum_count

The report table “Top tables by new-page updated tuples” shows top tables by the number of rows updated where the successor version goes onto a *new* heap page, leaving behind an original version with a `t_ctid` field that points to a different heap page. These are always non-HOT updates. [Table G.46](#) lists columns of this report table.

Table G.46. Top tables by new-page updated tuples

Column	Description
DB	Database name for the table
Tablespace	Name of the tablespace where the table is located
Schema	Schema name for the table
Table	Table name
NP Upd	Number of rows updated to a new heap page
%Upd	Number of new-page updated rows as the percentage of all rows updated
Upd	Number of rows updated, including HOT
Upd (HOT)	Number of rows HOT updated (i.e., with no separate index update required)

The report table “Top growing tables” shows top tables by growth. The data is based on the `pg_stat_all_tables` view. When there are no relation sizes collected with `pg_relation_size()`, relation-size estimates are based on the `pg_class.relpages` field. Since such values are less accurate, they are shown in square brackets. [Table G.47](#) lists columns of this report table.

Table G.47. Top growing tables

Column	Description	Field/Calculation
DB	Database name for the table	

Postgres Pro Modules
and Extensions Shipped
as Individual Packages

Column	Description	Field/Calculation
Tablespace	Name of the tablespace where the table is located	
Schema	Schema name for the table	
Table	Table name	
Size	Table size at the time of the last sample in the report interval	<code>pg_table_size()</code> - <code>pg_relation_size(toast)</code>
Growth	Table growth	
Ins	Number of rows inserted	<code>n_tup_ins</code>
Upd	Number of rows updated, including HOT	<code>n_tup_upd</code>
Del	Number of rows deleted	<code>n_tup_del</code>
Upd (HOT)	Number of rows HOT updated	<code>n_tup_hot_upd</code>

In the report table “Top indexes by blocks fetched”, blocks fetched include index blocks processed from disk (read) and from shared buffers (hit). The data is based on the `pg_statio_all_indexes` view. [Table G.48](#) lists columns of this report table.

Table G.48. Top indexes by blocks fetched

Column	Description	Field/Calculation
DB	Database name for the index	
Tablespace	Name of the tablespace where the index is located	
Schema	Schema name for the underlying table	
Table	Underlying table name	
Index	Index name	
Scans	Number of index scans initiated on this index	<code>idx_scan</code>
Blks	Number of blocks fetched for this index	<code>idx_blks_read</code> + <code>idx_blks_hit</code>
%Total	Percentage of blocks fetched for this index in all blocks fetched in the cluster	

The report table “Top indexes by blocks read” is also based on the `pg_statio_all_indexes` and `pg_stat_all_indexes` views. [Table G.49](#) lists columns of this report table.

Table G.49. Top indexes by blocks read

Column	Description	Field/Calculation
DB	Database name for the index	
Tablespace	Name of the tablespace where the index is located	
Schema	Schema name for the underlying table	
Table	Underlying table name	
Index	Index name	

Postgres Pro Modules
and Extensions Shipped
as Individual Packages

Column	Description	Field/Calculation
Scans	Number of index scans initiated on this index	idx_scan
Blk Reads	Number of disk blocks read from this index	idx_blks_read
%Total	Percentage of disk blocks read from this index in all disk blocks read in the cluster	
Hits (%)	Percentage of index blocks got from buffers in all index blocks got for this index	

The report table “Top growing indexes” shows top indexes by growth. The table uses data from the [pg_stat_all_tables](#) and [pg_stat_all_indexes](#) views. When there are no relation sizes collected with [pg_relation_size\(\)](#), relation-size estimates are based on the [pg_class.relpages](#) field. Since such values are less accurate, they are shown in square brackets. [Table G.50](#) lists columns of this report table.

Table G.50. Top growing indexes

Column	Description	Field/Calculation
DB	Database name for the index	
Tablespace	Name of the tablespace where the index is located	
Schema	Schema name for the underlying table	
Table	Underlying table name	
Index	Index name	
Index Size	Index size at the time of the last sample in the report interval	pg_relation_size()
Index Growth	Index growth during the report interval	
Table Ins	Number of rows inserted into the underlying table	n_tup_ins
Table Upd	Number of rows updated in the underlying table, without HOT	n_tup_upd - n_tup_hot_upd
Table Del	Number of rows deleted from the underlying table	n_tup_del

The report table “Unused indexes” shows top non-scanned indexes (during the report interval) by DML operations on underlying tables that caused index support. Constraint indexes are not counted. The table uses data from the [pg_stat_all_tables](#) view. [Table G.51](#) lists columns of this report table.

Table G.51. Unused indexes

Column	Description	Field/Calculation
DB	Database name for the index	
Tablespace	Name of the tablespace where the index is located	
Schema	Schema name for the underlying table	

Postgres Pro Modules
and Extensions Shipped
as Individual Packages

Column	Description	Field/Calculation
Table	Underlying table name	
Index	Index name	
Index Size	Index size at the time of the last sample in the report interval	pg_relation_size()
Index Growth	Index growth during the report interval	
Table Ins	Number of rows inserted into the underlying table	n_tup_ins
Table Upd	Number of rows updated in the underlying table, without HOT	n_tup_upd - n_tup_hot_upd
Table Del	Number of rows deleted from the underlying table	n_tup_del

G.1.11.8. User function statistics

Tables in this section of the report show top functions in the cluster by statistics from the `pg_stat_user_functions` view. Times in the tables are provided in seconds.

The report table “Top functions by total time” shows top functions by the total time elapsed. The report table “Top functions by executions” shows top functions by the number of executions. The report table “Top trigger functions by total time” shows top trigger functions by the total time elapsed. [Table G.52](#) lists columns of these report tables.

Table G.52. User function statistics

Column	Description	Field/Calculation
DB	Database name for the function	
Schema	Schema name for the function	
Function	Function name	
Executions	Number of times this function has been called	calls
Total Time (s)	Total time spent in this function and all other functions called by it	total_time
Self Time (s)	Total time spent in this function itself, not including other functions called by it	self_time
Mean Time (s)	Mean time of a single function execution	total_time /calls
Mean self Time (s)	Mean self time of a single function execution	self_time /calls

G.1.11.9. Vacuum-related statistics

The report table “Top tables by vacuum time spent” is available if `pgpro_stats` can provide extended vacuum statistics. This table shows top tables by total time spent vacuuming them. The data is based on the `pgpro_stats_vacuum_tables` view. [Table G.53](#) lists columns of this report table.

Table G.53. Top tables by vacuum time spent

Column	Description	Field/Calculation
DB	Database name for the table	

Postgres Pro Modules
and Extensions Shipped
as Individual Packages

Column	Description	Field/Calculation
Tablespace	Name of the tablespace where the table is located	
Schema	Schema name for the table	
Table	Table name	
Total vacuum time	Total time of vacuuming this table	total_time
Delay vacuum time	Time spent sleeping in a vacuum delay point by vacuum operations performed on this table	delay_time
Read I/O time	Time spent reading database blocks by vacuum operations performed on this table	blk_read_time
Write I/O time	Time spent writing database blocks by vacuum operations performed on this table	blk_write_time
User CPU time	User CPU time of vacuuming tables of this database	user_time
System CPU time	System CPU time of vacuuming tables of this database	system_time
Vacuum count	Number of times this table has been manually vacuumed (not counting VACUUM FULL)	vacuum_count
Autovacuum count	Number of times this table has been vacuumed by the autovacuum daemon	autovacuum_count
Total fetched	Total number of database blocks fetched by vacuum operations performed on this table	total_blks_read + total_blks_hit
Heap fetched	Total number of blocks fetched from this table by vacuum operations performed on it	rel_blks_read + rel_blks_hit
Scanned	Number of pages examined by vacuum operations performed on this table	pages_scanned

The report table “Top indexes by vacuum time spent” is available if [pgpro_stats](#) can provide extended vacuum statistics. This table shows top indexes by total time spent vacuuming them. The data is based on the `pgpro_stats_vacuum_indexes` view. [Table G.54](#) lists columns of this report table.

Table G.54. Top indexes by vacuum time spent

Column	Description	Field/Calculation
DB	Database name for the table	
Tablespace	Name of the tablespace where the table is located	
Schema	Schema name for the table	
Table	Table name	
Index	Index name	
Total vacuum time	Total time of vacuuming this index	total_time

Postgres Pro Modules
and Extensions Shipped
as Individual Packages

Column	Description	Field/Calculation
Delay vacuum time	Time spent sleeping in a vacuum delay point by vacuum operations performed on this index	delay_time
Read I/O time	Time spent reading database blocks by vacuum operations performed on this index	blk_read_time
Write I/O time	Time spent writing database blocks by vacuum operations performed on this index	blk_write_time
User CPU time	User CPU time of vacuuming this index	user_time
System CPU time	System CPU time of vacuuming this index	system_time
Vacuum count	Number of times the underlying table has been manually vacuumed (not counting VACUUM FULL)	vacuum_count
Autovacuum count	Number of times the underlying table has been vacuumed by the autovacuum daemon	autovacuum_count
Total fetched	Total number of database blocks fetched by vacuum operations performed on the underlying table	total_blks_read + total_blks_hit
Index fetched	Total number of blocks fetched from this index by vacuum operations performed on it	rel_blks_read + rel_blks_hit

The report table “Top tables by blocks vacuum fetched” is available if [pgpro_stats](#) can provide extended vacuum statistics. This table shows top tables by blocks fetched vacuuming these tables. The data is based on the `pgpro_stats_vacuum_tables` view. [Table G.55](#) lists columns of this report table.

Table G.55. Top tables by blocks vacuum fetched

Column	Description	Field/Calculation
DB	Database name for the table	
Tablespace	Name of the tablespace where the table is located	
Schema	Schema name for the table	
Table	Table name	
DB fetched	Total number of database blocks fetched by vacuum operations performed on this table	total_blks_read + total_blks_hit
%Total	Total number of database blocks fetched by vacuum operations performed on this table as the percentage of all blocks fetched in the cluster	
DB read	Total number of database blocks read by vacuum operations performed on this table	total_blks_read

Postgres Pro Modules
and Extensions Shipped
as Individual Packages

Column	Description	Field/Calculation
%Total	Total number of database blocks read by vacuum operations performed on this table as the percentage of all blocks read in the cluster	
Heap fetched	Total number of blocks fetched from this table by vacuum operations performed on it	rel_blks_read + rel_blks_hit
%Rel	Total number of table blocks fetched by vacuum operations performed on this table as the percentage of all blocks fetched from this table	
Heap read	Total number of blocks read from this table by vacuum operations performed on it	rel_blks_read
%Rel	Total number of table blocks read by vacuum operations performed on this table as the percentage of all blocks read from this table	
Scanned	Number of pages examined by vacuum operations performed on this table	pages_scanned

The report table “Top indexes by blocks vacuum fetched” is available if [pgpro_stats](#) can provide extended vacuum statistics. This table shows top indexes by blocks fetched vacuuming underlying tables. The data is based on the `pgpro_stats_vacuum_indexes` view. [Table G.56](#) lists columns of this report table.

Table G.56. Top indexes by blocks vacuum fetched

Column	Description	Field/Calculation
DB	Database name for the table	
Tablespace	Name of the tablespace where the table is located	
Schema	Schema name for the table	
Table	Table name	
Index	Index name	
DB fetched	Total number of database blocks fetched by vacuum operations performed on this index	total_blks_read + total_blks_hit
%Total	Total number of database blocks fetched by vacuum operations performed on this index as the percentage of all blocks fetched in the cluster

The report table “Top tables by dead tuples vacuum left” is available if [pgpro_stats](#) can provide extended vacuum statistics. This table shows top tables by the number of dead tuples left by vacuum due to their visibility in transactions. The data is based on the `pgpro_stats_vacuum_tables` view. [Table G.59](#) lists columns of this report table.

Table G.59. Top tables by dead tuples vacuum left

Column	Description	Field/Calculation
DB	Database name for the table	
Tablespace	Name of the tablespace where the table is located	
Schema	Schema name for the table	
Table	Table name	
Dead tuples left	Total number of dead tuples vacuum operations left in this table due to their visibility in transactions	<code>dead_tuples</code>
Dead tuples deleted	Total number of dead tuples vacuum operations deleted from this table	<code>tuples_deleted</code>
%Eff	Vacuum efficiency in terms of deleted tuples. This is the percentage of dead tuples deleted from this table in all dead tuples to be deleted from this table.	$\text{tuples\_deleted} * 100 / (\text{tuples\_deleted} + \text{dead\_tuples})$
Tuples del	Number of rows deleted	<code>pg_stat_all_tables .n_tup_del</code>
Tuples upd	Number of rows updated (includes HOT updated rows)	<code>pg_stat_all_tables .n_tup_upd</code>
Vacuum	Number of times this table has been manually vacuumed (not counting <code>VACUUM FULL</code>)	<code>vacuum_count</code>
Autovacuum	Number of times this table has been vacuumed by the autovacuum daemon	<code>autovacuum_count</code>

The report table “Top tables by WAL size generated by vacuum” is available if [pgpro_stats](#) can provide extended vacuum statistics. This table shows top tables by the amount of WAL generated by vacuum operations performed on them. The data is based on the `pgpro_stats_vacuum_tables` view. [Table G.60](#) lists columns of this report table.

Table G.60. Top tables by WAL size generated by vacuum

Column	Description	Field/Calculation
DB	Database name for the table	
Tablespace	Name of the tablespace where the table is located	
Schema	Schema name for the table	

Postgres Pro Modules
and Extensions Shipped
as Individual Packages

Column	Description	Field/Calculation
Table	Table name	
WAL size	Total amount of WAL bytes generated by vacuum operations performed on this table	wal_bytes
%Total	Total amount of WAL bytes generated by vacuum operations performed on this table as the percentage of all WAL generated in the cluster	
WAL FPI	Total number of WAL full page images generated by vacuum operations performed on this table	wal_fpi
Scanned blocks	Number of pages examined by vacuum operations performed on this table	pages_scanned
Dirtied blocks	Number of database blocks dirtied by vacuum operations performed on this table	total_blks_dirtied
Removed blocks	Number of pages removed by vacuum operations performed on this table	pages_removed
Vacuum	Number of times this table has been manually vacuumed (not counting <code>VACUUM FULL</code>)	vacuum_count
Autovacuum	Number of times this table has been vacuumed by the autovacuum daemon	autovacuum_count

The report table “Top tables by vacuum operations” shows top tables by the number of vacuum operations performed (`vacuum_count + autovacuum_count`). The data is based on the [pg_stat_all_tables](#) view. [Table G.61](#) lists columns of this report table.

Table G.61. Top tables by vacuum operations

Column	Description	Field/Calculation
DB	Database name for the table	
Tablespace	Name of the tablespace where the table is located	
Schema	Schema name for the table	
Table	Table name	
Vacuum count	Number of times this table has been manually vacuumed (not counting <code>VACUUM FULL</code>)	vacuum_count
Autovacuum count	Number of times this table has been vacuumed by the autovacuum daemon	autovacuum_count
Ins	Number of rows inserted	n_tup_ins
Upd	Number of rows updated (includes HOT updated rows)	n_tup_upd
Del	Number of rows deleted	n_tup_del

Postgres Pro Modules
and Extensions Shipped
as Individual Packages

Column	Description	Field/Calculation
Upd (HOT)	Number of rows HOT updated	n_tup_hot_upd

The report table “Top tables by analyze operations” shows top tables by the number of analyze operations performed (`analyze_count + autoanalyze_count`). The data is based on the `pg_stat_all_tables` view. Table G.62 lists columns of this report table.

Table G.62. Top tables by analyze operations

Column	Description	Field/Calculation
DB	Database name for the table	
Tablespace	Name of the tablespace where the table is located	
Schema	Schema name for the table	
Table	Table name	
Analyze count	Number of times this table has been manually analyzed	<code>analyze_count</code>
Autoanalyze count	Number of times this table has been analyzed by the autovacuum daemon	<code>autoanalyze_count</code>
Ins	Number of rows inserted	<code>n_tup_ins</code>
Upd	Number of rows updated, including HOT	<code>n_tup_upd</code>
Del	Number of rows deleted	<code>n_tup_del</code>
Upd (HOT)	Number of rows HOT updated	<code>n_tup_hot_upd</code>

The report table “Top indexes by estimated vacuum load” shows top indexes by estimated implicit vacuum load. This load is calculated as the number of vacuum operations performed on the underlying table multiplied by the index size. The data is based on the `pg_stat_all_indexes` view. When there are no relation sizes collected with `pg_relation_size()`, relation-size estimates are based on the `pg_class.relpages` field. Since such values are less accurate, they are shown in square brackets. Table G.63 lists columns of this report table.

Table G.63. Top indexes by estimated vacuum load

Column	Description	Field/Calculation
DB	Database name for the index	
Tablespace	Name of the tablespace where the index is located	
Schema	Schema name for the underlying table	
Table	Underlying table name	
Index	Index name	
~Vacuum bytes	Vacuum load estimation	$(\text{vacuum\_count} + \text{autovacuum\_count}) * \text{index\_size}$
Vacuum count	Number of times this table has been manually vacuumed (not counting <code>VACUUM FULL</code>)	<code>vacuum_count</code>
Autovacuum count	Number of times this table has been vacuumed by the autovacuum daemon	<code>autovacuum_count</code>

Postgres Pro Modules
and Extensions Shipped
as Individual Packages

Column	Description	Field/Calculation
IX size	Average index size during the report interval	
Relsize	Average relation size during the report interval	

The report table “Top tables by dead tuples ratio” shows top tables larger than 5 MB by the ratio of dead tuples. Statistics are valid for the last sample in the report interval. The data is based on the [pg_stat_all_tables](#) view. When there are no relation sizes collected with [pg_relation_size\(\)](#), relation-size estimates are based on the [pg_class.relpages](#) field. Since such values are less accurate, they are shown in square brackets. [Table G.64](#) lists columns of this report table.

Table G.64. Top tables by dead tuples ratio

Column	Description	Field/Calculation
DB	Database name for the table	
Schema	Schema name for the table	
Table	Table name	
Live	Estimated number of live rows	n_live_tup
Dead	Estimated number of dead rows	n_dead_tup
%Dead	Percentage of dead rows in all table rows	
Last AV	Last time at which this table was vacuumed by the autovacuum daemon	last_autovacuum
Size	Table size	pg_table_size() - pg_relation_size(toast)

The report table “Top tables by modified tuples ratio” shows top tables larger than 5 MB by the ratio of modified tuples. Statistics are valid for the last sample in the report interval. The data is based on the [pg_stat_all_tables](#) view. When there are no relation sizes collected with [pg_relation_size\(\)](#), relation-size estimates are based on the [pg_class.relpages](#) field. Since such values are less accurate, they are shown in square brackets. [Table G.65](#) lists columns of this report table.

Table G.65. Top tables by modified tuples ratio

Column	Description	Field/Calculation
DB	Database name for the table	
Schema	Schema name for the table	
Table	Table name	
Live	Estimated number of live rows	n_live_tup
Dead	Estimated number of dead rows	n_dead_tup
Mod	Estimated number of rows modified since this table was last analyzed	n_mod_since_analyze
%Mod	Percentage of modified rows in all table rows	
Last AA	Last time at which this table was analyzed by the autovacuum daemon	last_autoanalyze

Postgres Pro Modules and Extensions Shipped as Individual Packages

Column	Description	Field/Calculation
Size	Table size	<code>pg_table_size()</code> - <code>pg_relation_size(toast)</code>

G.1.11.10. Cluster settings during the report interval

This section of the report contains a table with Postgres Pro GUC parameters, values of functions `version()`, `pg_postmaster_start_time()`, `pg_conf_load_time()` and the `system_identifier` field of the `pg_control_system()` function during the report interval. The data in the table is grouped under `Defined settings` and `Default settings`. [Table G.66](#) lists columns of this report table.

Table G.66. Cluster settings during the report interval

Column	Description
Setting	Name of the parameter
reset_val	<code>reset_val</code> field of the <code>pg_settings</code> view. Settings changed during the report interval are shown in bold font.
Unit	Unit of the setting
Source	Configuration file where this setting is defined, semicolon, line number
Notes	Timestamp of the sample where this value was first observed

G.1.11.11. Extension versions during the report interval

This section of the report contains a table that lists installed extension versions found in databases during the report interval. `First seen` and `Last seen` columns are not shown if the extension versions have not changed during the report interval. [Table G.67](#) lists columns of this report table.

Table G.67. Extension versions during the report interval

Column	Description
Name	Extension name
DB	Database name
First seen	Timestamp of the sample where this extension version appeared first
Last seen	Timestamp of the sample where this extension version appeared last
Version	Version name of the extension

G.1.12. pgpro_pwr Diagnostic Tools

`pgpro_pwr` provides self-diagnostic tools.

G.1.12.1. Collecting Detailed Timing Statistics for Sampling Procedures

`pgpro_pwr` collects detailed timing statistics of taking samples when the `pgpro_pwr.track_sample_timings` parameter is on. You can get the results from the `v_sample_timings` view. [Table G.68](#) lists columns of this view.

Table G.68. `v_sample_timings` View

Column	Description
server_name	Name of the server
sample_id	Sample identifier

Postgres Pro Modules
and Extensions Shipped
as Individual Packages

Column	Description
sample_time	Time when the sample was taken
sampling_event	Sampling stage. See Table G.69 for descriptions of sampling stages.
time_spent	Time spent in the event

Table G.69. sampling_event Description

Event	Description
total	Taking the sample (all stages)
connect	Making dblink connection to the server
get server environment	Getting server GUC parameters, available extensions, etc.
collect database stats	Querying the pg_stat_database view for statistics on databases
calculate database stats	Calculating differential statistics on databases since the previous sample
collect tablespace stats	Querying the pg_tablespace view for statistics on tablespaces
collect statement stats	Collecting statistics on statements using the pg-pro_stats and pg_stat_kcache extensions
query pg_stat_bgwriter	Collecting cluster statistics using the pg_stat_bgwriter view
query pg_stat_archiver	Collecting cluster statistics using the pg_stat_archiver view
collect object stats	Collecting statistics on database objects. Includes events from Table G.70 .
maintain repository	Executing support routines
calculate tablespace stats	Calculating differential statistics on tablespaces
calculate object stats	Calculating differential statistics on database objects. Includes events from Table G.71 .
calculate cluster stats	Calculating cluster differential statistics
calculate archiver stats	Calculating archiver differential statistics
delete obsolete samples	Deleting obsolete baselines and samples

Table G.70. Events of Collecting Statistics on Database Objects

Event	Description
db:dbname collect tables stats	Collecting statistics on tables for the <i>dbname</i> database
db:dbname collect indexes stats	Collecting statistics on indexes for the <i>dbname</i> database
db:dbname collect functions stats	Collecting statistics on functions for the <i>dbname</i> database

Table G.71. Events of Calculating Differences of Statistics on Database Objects

Event	Description
calculate tables stats	Calculating differential statistics on tables of all databases

Event	Description
calculate indexes stats	Calculating differential statistics on indexes of all databases
calculate functions stats	Calculating differential statistics on functions of all databases

G.1.13. Important Notes

When using the `pgpro_pwr` extension, be aware of the following:

- Postgres Pro collects execution statistics *after* the execution is complete. If a single execution of a statement lasts for several samples, it will only affect statistics of the last sample (in which the execution completed). Besides, statistics on statements that are still running are unavailable. Maintenance processes, such as vacuum and checkpoint, will update the statistics only on completion.
- Resetting any Postgres Pro statistics may affect the accuracy of the next sample.
- Exclusive locks on relations conflict with calculation of the relation size. If the `take_sample()` function is unable to acquire a lock for a short period of time (3 seconds), it will fail and no sample will be generated.

G.2. `pgpro_stats` — a means for tracking planning and execution statistics of all SQL statements executed by a server

The `pgpro_stats` extension provides a means for tracking planning and execution statistics of all SQL statements executed by a server. It is based on the `pg_stat_statements` module and provides the following additional functionality:

- Storing query plans in addition to query statements.
- Configuring sample rate for statistics collection to reduce overhead.
- Calculating wait event statistics for executed queries.
- Calculating resource usage statistics of statement planning and execution.
- Calculating cache invalidation statistics.
- Calculating additional archiver statistics.
- Providing an interface to statistics about vacuuming databases, tables, and indexes collected by the core system.
- Tracing of application sessions.
- Creating views that emulate other extensions.

Note

When the server gets shut down, `pgpro_stats` saves the collected statistics to two dump files on disk in the format that depends on the number and order of columns in the `pgpro_stats_statements` and `pgpro_stats_totals` views. If this format has changed in a new `pgpro_stats` version, during the first server restart after upgrading the extension, the saved statistics will fail to be read with an error reported to the log:

```
LOG:  pgpro_stats: could not load statements data file of obsolete format
      "pg_stat/pgpro_stats.stat"
```

or

```
LOG:  pgpro_stats: could not load statements data file of obsolete format
      "pg_stat/pgpro_stats_totals.stat"
```

The contents of the files will be ignored, and respective statistics will be nullified. To learn whether the format has changed, see the [Release Notes](#) for pgpro_stats version being installed. To retain the previously collected statistics, download them as CSV files before upgrading.

The background information, along with views and types, related to calculating cache invalidation statistics is provided in a separate section [Section G.2.9](#).

G.2.1. Limitations

- pgpro_stats can sometimes fail to match identical parameters in the query statement and the corresponding query plan.
- Some SPI queries are not included into statistics.
- Texts and plans of some SPI queries are not normalized.
- pgpro_stats is incompatible with [pg_stat_statements](#), as well as other extensions that use parser, planner, or executor hooks to modify parse and plan trees and execution of the queries. Moreover, if both pgpro_stats and [pg_stat_statements](#) are on the list of shared_preload_libraries, the database server will not start. Note also that in order to dump the final versions of the queries and plans, pgpro_stats should be the last on the list of shared_preload_libraries, but some existing extensions, such as pg_pathman, will not work at all unless they are the last on this list.
- pgpro_stats may not work correctly with third-party extensions that produce CustomScan and ForeignScan nodes.

G.2.2. Installation and Setup

pgpro_stats is provided with Postgres Pro Standard as a separate pre-built package pgpro-stats-std-16 (for the detailed installation instructions, see [Chapter 16](#)). Once you have pgpro_stats installed, complete the following steps to enable pgpro_stats:

1. Add pgpro_stats to the [shared_preload_libraries](#) parameter in the postgresql.conf file:

```
shared_preload_libraries = 'pgpro_stats'
```

2. Restart the Postgres Pro Standard instance for the changes to take effect.

Once the server is reloaded, pgpro_stats starts tracking statistics across all databases of the cluster. If required, you can change the scope of statistics collection or disable it altogether using pgpro_stats [configuration parameters](#).

3. To access the collected statistics, you have to create pgpro_stats extension:

```
CREATE EXTENSION pgpro_stats;
```

In addition, query identifier calculation must be enabled in order for pgpro_stats to be active, which is done automatically if [compute_query_id](#) is set to auto or on, or any third-party module that calculates query identifiers is loaded.

G.2.3. Usage

- [Collecting Statistics on Query Statements and Plans](#)
- [Monitoring Custom Metrics](#)

G.2.3.1. Collecting Statistics on Query Statements and Plans

Once installed, the pgpro_stats extension starts collecting statistics on the executed statements. The collected data is similar to the one provided by [pg_stat_statements](#), but also includes information on

query plans and wait events for each query type. The statistics is saved into an in-memory ring buffer and is accessible through the `pgpro_stats_statements` view.

By default, `pgpro_stats` collects statistics on all the executed statements that satisfy the `pgpro_stats.track` and `pgpro_stats.track_utility` settings. If performance is a concern, you can set a sample rate for queries using the `pgpro_stats.query_sample_rate` parameter, and `pgpro_stats` will randomly select queries for statistics calculation at the specified rate.

To collect statistics on wait events, `pgpro_stats` uses time-based sampling. Wait events are sampled at the time interval specified by the `pgpro_stats.profile_period` parameter, which is set to 10ms by default. If the sampling shows that the process is waiting, the `pgpro_stats.profile_period` value is added to the wait event duration. Thus, time estimation for each wait event remains valid even if the `pgpro_stats.profile_period` parameter value has changed. If you are not interested in wait event statistics, you can disable wait event sampling by setting the `pgpro_stats.enable_profile` parameter to `false`.

`pgpro_stats_statements.plans` and `pgpro_stats_statements.calls` aren't always expected to match because planning and execution statistics are updated at their respective end phase, and only for successful operations. For example, if a statement is successfully planned but fails during the execution phase, only its planning statistics will be updated. If planning is skipped because a cached plan is used, only its execution statistics will be updated.

As an example, let's create a table with some random data and build an index on this table:

```
CREATE TABLE test AS (SELECT i, random() x FROM generate_series(1,1000000) i);
CREATE INDEX test_x_idx ON test (x);
```

Now run the following query several times using different values for `:x_min` and `:x_max`:

```
select * from test where x >= :x_min and x <= :x_max;
```

The collected statistics should appear in the `pgpro_stats_statements` view:

```
SELECT queryid, query, planid, plan, wait_stats FROM pgpro_stats_statements WHERE query
LIKE 'select * from test where%';
```

```
-[ RECORD
```

```
1 ]-----
queryid      | 1109491335754870054

```

G.2.3.2. Monitoring Custom Metrics

With `pgpro_stats`, you can define custom metrics to be monitored. The collected data will be saved into an in-memory ring buffer and then sent to a monitoring system. Unlike direct polling of a database by a monitoring system that can lose some data if the connection is interrupted, this approach allows to get all the collected data regardless of connection issues, as long as this data is still available in the ring buffer.

To set up a custom metric to collect, do the following:

1. For each metric, define all configuration parameters listed in [Section G.2.7.2](#). You must specify a unique numeric identifier of each metric in the parameter names.

For example, to monitor index bloating each 60 seconds, you can define a new metric by setting metrics-related parameters as follows:

```

pgpro_stats.metric_1_name = index_bloat
pgpro_stats.metric_1_query = 'select iname, ibloat, ipages from bloat'
pgpro_stats.metric_1_db = 'postgres'
pgpro_stats.metric_1_user = postgres
pgpro_stats.metric_1_period = '60s'

```

2. Restart the server.

`pgpro_stats` starts collecting statistics on executed statements and saves it into the ring buffer, and the collected data appears in the `pgpro_stats_metrics` view:

```
SELECT * FROM pgpro_stats_metrics;
```

Once the new metric is added, its parameters can be changed without a server restart by simply reloading the `postgresql.conf` configuration file.

3. If required, set up data export to a monitoring system of your choice.

G.2.4. Views

G.2.4.1. The `pgpro_stats_statements` View

The statistics gathered by the module are made available via a view named `pgpro_stats_statements`. This view contains one row for each distinct database ID, user ID and query ID (up to the maximum number of distinct statements that the module can track). The columns of the view are shown in [Table G.72](#).

Table G.72. pgpro_stats_statements Columns

Name	Type	References	Description
userid	oid	pg_authid .oid	OID of user who executed the statement
dbid	oid	pg_database .oid	OID of database in which the statement was executed
toplevel	bool		True if the query was executed as a top-level statement (always true if pgpro_stats.track is set to <code>top</code>)
queryid	bigint		Internal hash code, computed from the statement's parse tree
planid	bigint		Internal hash code, computed from the statement's plan tree
query	text		Text of a representative statement
plan	text		The text of the query plan, in the format defined by the pgpro_stats.plan_format configuration parameter
plans	int8		Number of times the statement was planned (if pgpro_stats.track_planning is enabled, otherwise zero)
total_plan_time	float8		Total time spent planning the statement, in milliseconds (if pgpro_stats.track_planning is enabled, otherwise zero).
min_plan_time	float8		Minimum time spent planning the statement, in milliseconds (if pgpro_stats.track_planning is enabled, otherwise zero)
max_plan_time	float8		Maximum time spent planning the statement, in milliseconds (if pgpro_stats.track_planning is enabled, otherwise zero)
mean_plan_time	float8		Mean time spent planning the statement, in milliseconds (if pgpro_stats.track_planning

Postgres Pro Modules
and Extensions Shipped
as Individual Packages

Name	Type	References	Description
			is enabled, otherwise zero)
stddev_plan_time	float8		Population standard deviation of time spent planning the statement, in milliseconds (if <code>pgpro_stats.track_planning</code> is enabled, otherwise zero)
plan_rusage	pgpro_stats_rusage		Resource usage statistics of the statement planning.
calls	int8		Number of times the statement was executed
total_exec_time	float8		Total time spent executing the statement, in milliseconds
min_exec_time	float8		Minimum time spent executing the statement, in milliseconds
max_exec_time	float8		Maximum time spent executing the statement, in milliseconds
mean_exec_time	float8		Mean time spent executing the statement, in milliseconds
stddev_exec_time	float8		Population standard deviation of time spent executing the statement, in milliseconds
exec_rusage	pgpro_stats_rusage		Resource usage statistics of the statement execution.
rows	int8		Total number of rows retrieved or affected by the statement
shared_blks_hit	int8		Total number of shared block cache hits by the statement
shared_blks_read	int8		Total number of shared blocks read by the statement
shared_blks_dirtied	int8		Total number of shared blocks dirtied by the statement
shared_blks_written	int8		Total number of shared blocks written by the statement

Postgres Pro Modules
and Extensions Shipped
as Individual Packages

Name	Type	References	Description
local_blks_hit	int8		Total number of local block cache hits by the statement
local_blks_read	int8		Total number of local blocks read by the statement
local_blks_dirtied	int8		Total number of local blocks dirtied by the statement
local_blks_written	int8		Total number of local blocks written by the statement
temp_blks_read	int8		Total number of temp blocks read by the statement
temp_blks_written	int8		Total number of temp blocks written by the statement
shared_blk_read_time	float8		Total time the statement spent reading shared blocks, in milliseconds (if track_io_timing is enabled, otherwise zero)
shared_blk_write_time	float8		Total time the statement spent writing shared blocks, in milliseconds (if track_io_timing is enabled, otherwise zero)
local_blk_read_time	float8		Total time the statement spent reading local blocks, in milliseconds (if track_io_timing is enabled, otherwise zero). In Postgres Pro versions lower than 17, contains zero.
local_blk_write_time	float8		Total time the statement spent writing local blocks, in milliseconds (if track_io_timing is enabled, otherwise zero). In Postgres Pro versions lower than 17, contains zero.
temp_blk_read_time	float8		Total time the statement spent reading temp blocks, in milliseconds (if track_io_timing is enabled, otherwise zero). In Postgres Pro versions lower than 15, contains zero.

Postgres Pro Modules
and Extensions Shipped
as Individual Packages

Name	Type	References	Description
temp_blk_write_time	float8		Total time the statement spent writing temp blocks, in milliseconds (if track_io_timing is enabled, otherwise zero). In Postgres Pro versions lower than 15, contains zero.
wal_records	int8		Total number of WAL records generated by the statement
wal_fpi	int8		Total number of WAL full page images generated by the statement
wal_bytes	numeric		Total amount of WAL bytes generated by the statement
jit_functions	int8		Total number of functions JIT-compiled by the statement. In Postgres Pro versions lower than 15, contains zero.
jit_generation_time	float8		Total time spent by the statement on generating JIT code, in milliseconds. In Postgres Pro versions lower than 15, contains zero.
jit_inlining_count	int8		Number of times functions used in the statement have been inlined. In Postgres Pro versions lower than 15, contains zero.
jit_inlining_time	float8		Total time spent by the statement on inlining functions, in milliseconds. In Postgres Pro versions lower than 15, contains zero.
jit_optimization_count	int8		Number of times the statement has been optimized. In Postgres Pro versions lower than 15, contains zero.
jit_optimization_time	float8		Total time spent by the statement on optimizing, in milliseconds. In Postgres Pro versions lower than 15, contains zero.
jit_emission_count	int8		Number of times code has been emitted by the

and Extensions Shipped
as Individual Packages

Name	Type	References	Description
			statement. In Postgres Pro versions lower than 15, contains zero.
jit_emission_time	float8		Total time spent by the statement on emitting code, in milliseconds. In Postgres Pro versions lower than 15, contains zero.
jit_deform_count	int8		Total number of tuple deform functions JIT-compiled by the statement. In Postgres Pro versions lower than 17, contains zero.
jit_deform_time	float8		Total time spent by the statement on JIT-compiling tuple deform functions, in milliseconds. In Postgres Pro versions lower than 17, contains zero.
wait_stats	jsonb		A <code>jsonb</code> object containing statistics on wait events, for each execution of the query that uses the corresponding plan. Each statistic is provided in milliseconds and is a multiple of the pgpro_stats.profile_period configuration parameter.
inval_msgs	pgpro_stats_inval_msgs		Number of cache invalidation messages by type generated by the statement (if this is supported by the server, otherwise zero).
stats_since	timestamp with time zone		Time at which statistics gathering started for this statement
minmax_stats_since	timestamp with time zone		Time at which min/max statistics gathering started for this statement (fields <code>min_plan_time</code> , <code>max_plan_time</code> , <code>min_exec_time</code> and <code>max_exec_time</code>)

Take into account that like [pg_stat_statements](#), `pgpro_stats` normalizes into one record those DML queries (containing `SELECT`, `INSERT`, `UPDATE`, `DELETE` and `MERGE` commands) that have equivalent structures according to some internal hash value. Being compared this way, two queries are normally considered equal if they are semantically equivalent up to constants included in the queries. When the value

of a constant in a query is ignored for comparison with other queries, this constant is replaced in the `pgpro_stats` output with a symbol of a parameter, such as, `$k`, where `k` is a positive integer. If a query already contains parameters, the initial value of `k` equals the number following the last number of a `$n` parameter in the original query text. If there are no parameters, the initial value of `k` equals 1. Note that sometimes hidden parameter symbols affect this numbering. For example, PL/pgSQL uses such hidden symbols to insert values of function local variables into queries, so a PL/pgSQL statement `SELECT i + 1 INTO j` will be represented as `SELECT i + $2` in the normalized query text.

`pgpro_stats` uses a similar technique to normalize plan texts. When doing so, an attempt is made to associate numbers of constants in the plan text with the corresponding numbers of constants in the query text. If such an attempt appears unsuccessful for a certain constant in the plan text, it is assigned the number following the maximum number of a constant replaced in the query text. For example, consider the query:

```
SELECT 1::int, 'abc'::VARCHAR(3), 2::int;
```

`pgpro_stats` will replace numbers of constants in the query text and in the text of the corresponding plan as follows:

```
postgres=# SELECT query, plan FROM pgpro_stats_statements;
               query                               |                               plan
-----
+-----+-----+
SELECT $1::int, $2::VARCHAR(3), $3::int          | Result
      +                                           |
      +                                           |   Output: $1, $4, $3
```

In this plan text, it appeared possible to associate constants numbered 1 and 3 from the query text, but not the constant numbered 2, and the latter was replaced with the number following the maximum number in the query text, that is, number 4.

Replacement of numbers in plan texts has an exception for version numbers of XML documents. If in the original query such a number is represented with a constant, e.g., '1.0', it is retained as is in the plan text rather than replaced with `$k`. If the version number of an XML document is represented with an expression, replacement of constants follows usual rules.

G.2.4.2. The `pgpro_stats_totals` View

The aggregate statistics gathered by the module are made available via a view named `pgpro_stats_totals`. This view contains one row for each distinct object (up to the maximum number of distinct objects that the module can track). The columns of the view are shown in [Table G.73](#).

Table G.73. `pgpro_stats_totals` Columns

Name	Type	Description
<code>object_type</code>	text	Type of the object for which aggregated statistics are collected: "cluster", "database", "user", "client_addr", "application", "backend", "session"
<code>object_id</code>	bigint	ID of the object: oid for databases and users, pid for backends, sid for sessions, NULL for others
<code>object_name</code>	text	Textual name of the object or NULL
<code>queries_planned</code>	int8	Number of queries planned
<code>total_plan_time</code>	float8	Total time spent in the planning of statements, in milliseconds

Postgres Pro Modules
and Extensions Shipped

as Individual Packages

Name	Type	Description
		sions lower than 15, contains zero.
jit_deform_count	int8	Total number of tuple deform functions JIT-compiled by the statements. In Postgres Pro versions lower than 17, contains zero.
jit_deform_time	float8	Total time spent by the statements on JIT-compiling tuple deform functions, in milliseconds. In Postgres Pro versions lower than 17, contains zero.
wait_stats	jsonb	A <code>jsonb</code> object containing statistics on wait events for each execution of the queries. Each statistic is provided in milliseconds and is a multiple of the pgpro_stats.profile_period configuration parameter.
inval_msgs	pgpro_stats_inval_msgs	Number of cache invalidation messages by type generated by the statements (if this is supported by the server, otherwise zero).
cache_resets	int4	Number of shared cache resets (only for cluster, databases and backends). Gets incremented for a backend when it receives a full cache reset message.
stats_since	timestamp with time zone	Time at which statistics gathering started for the statements

G.2.4.3. The `pgpro_stats_info` View

The statistics of the `pgpro_stats` module itself are tracked and made available via a view named `pgpro_stats_info`. This view contains only a single row. The columns of the view are shown in [Table G.74](#).

Table G.74. `pgpro_stats_info` Columns

Name	Type	Description
dealloc	bigint	Total number of times <code>pgpro_stats_statements</code> entries about the least-executed statements were deallocated because more distinct statements than pgpro_stats.max were observed
stats_reset	timestamp with time zone	Time at which all statistics in the pgpro_stats_statements view were last reset

G.2.4.4. The `pgpro_stats_metrics` View

The metrics gathered by `pgpro_stats` are displayed in the `pgpro_stats_metrics` view. The table below describes the columns of the view.

Table G.75. pgpro_stats_metrics Columns

Name	Type	Description
metric_number	int4	A unique ID of the collected metric assigned by user. This ID is included into parameter names that define the metric.
metric_name	text	The name of the metric defined by the <code>pgpro_stats.metric_N_name</code> parameter
db_name	text	The name of the database for which a particular metric was collected
ts	timestampz	The time when the metric value got calculated
value	jsonb	The result of the query used for metric measurement. It is serialized in <code>jsonb</code> as an array of objects received via <code>to_jsonb(resulting_row)</code> . If an error occurs, a single object is returned that contains <code>code</code> , <code>message</code> , <code>detail</code> , and <code>hint</code> fields.

G.2.4.5. The pgpro_stats_archiver View

The `pgpro_stats_archiver` view will contain one row showing data about the archiver process of the cluster.

Table G.76. pgpro_stats_archiver Columns

Column	Type	Description
archived_count	bigint	Number of WAL files that have been successfully archived
last_archived_wal	text	Name of the last WAL file successfully archived
last_archived_time	timestamp with time zone	Time of the last successful archive operation
failed_count	bigint	Number of failed attempts for archiving WAL files
last_failed_wal	text	Name of the WAL file of the last failed archival operation
last_failed_time	timestamp with time zone	Time of the last failed archival operation
active_time	int8	Overall time that the archiver process was active
archive_command_time	int8	Overall execution time of the archive command
stats_reset	timestamp with time zone	Time at which these statistics were last reset

G.2.4.6. The pgpro_stats_vacuum_database View

Important

Starting with Postgres Pro 16, this view contains no data because the statistics to be displayed are available through the catalog view `pg_stats_vacuum_database` (see [System Views](#) for details).

The `pgpro_stats_vacuum_database` view will contain one row for each database in the current cluster, showing statistics about vacuuming that database. These statistics are collected by the core system as explained in [Section 26.2](#). The table below describes the columns of the view.

Table G.77. pgpro_stats_vacuum_database Columns

Column	Type	Description
<code>dbid</code>	<code>oid</code>	OID of a database
<code>total_blks_read</code>	<code>int8</code>	Number of database blocks read by vacuum operations performed on this database
<code>total_blks_hit</code>	<code>int8</code>	Number of times database blocks were found in the buffer cache by vacuum operations performed on this database
<code>total_blks_dirtied</code>	<code>int8</code>	Number of database blocks dirtied by vacuum operations performed on this database
<code>total_blks_written</code>	<code>int8</code>	Number of database blocks written by vacuum operations performed on this database
<code>wal_records</code>	<code>int8</code>	Total number of WAL records generated by vacuum operations performed on this database
<code>wal_fpi</code>	<code>int8</code>	Total number of WAL full page images generated by vacuum operations performed on this database
<code>wal_bytes</code>	<code>numeric</code>	Total amount of WAL bytes generated by vacuum operations performed on this database
<code>blk_read_time</code>	<code>float8</code>	Time spent reading database blocks by vacuum operations performed on this database, in milliseconds (if track_io_timing is enabled, otherwise zero)
<code>blk_write_time</code>	<code>float8</code>	Time spent writing database blocks by vacuum operations performed on this database, in milliseconds (if track_io_timing is enabled, otherwise zero)
<code>delay_time</code>	<code>float8</code>	Time spent sleeping in a vacuum delay point by vacuum operations performed on this database, in milliseconds (see Section 18.4.4 for details)

Postgres Pro Modules
and Extensions Shipped
as Individual Packages

Column	Type	Description
system_time	float8	System CPU time of vacuuming this database, in milliseconds
user_time	float8	User CPU time of vacuuming this database, in milliseconds
total_time	float8	Total time of vacuuming this database, in milliseconds
interrupts	int4	Number of times vacuum operations performed on this database were interrupted on any errors

G.2.4.7. The pgpro_stats_vacuum_tables View

Important

Starting with Postgres Pro 16, this view contains no data because the statistics to be displayed are available through the catalog view `pg_stats_vacuum_tables` (see [System Views](#) for details).

The `pgpro_stats_vacuum_tables` view will contain one row for each table in the current database (including TOAST tables), showing statistics about vacuuming that specific table. These statistics are collected by the core system as explained in [Section 26.2](#). The table below describes the columns of the view.

Table G.78. pgpro_stats_vacuum_tables Columns

Column	Type	Description
relid	oid	OID of a table
schema	name	Name of the schema this table is in
relname	name	Name of this table
total_blks_read	int8	Number of database blocks read by vacuum operations performed on this table
total_blks_hit	int8	Number of times database blocks were found in the buffer cache by vacuum operations performed on this table
total_blks_dirtied	int8	Number of database blocks dirtied by vacuum operations performed on this table
total_blks_written	int8	Number of database blocks written by vacuum operations performed on this table
rel_blks_read	int8	Number of blocks vacuum operations read from this table
rel_blks_hit	int8	Number of times blocks of this table were already found in the buffer cache by vacuum operations, so that a read was not necessary (this only includes hits in the Postgres Pro buffer cache, not the operating system's file system cache)

Postgres Pro Modules
and Extensions Shipped
as Individual Packages

Column	Type	Description
pages_scanned	int8	Number of pages examined by vacuum operations performed on this table
pages_removed	int8	Number of pages removed from the physical storage by vacuum operations performed on this table
pages_frozen	int8	Number of times vacuum operations marked pages of this table as all-frozen in the visibility map
pages_all_visible	int8	Number of times vacuum operations marked pages of this table as all-visible in the visibility map
tuples_deleted	int8	Number of dead tuples vacuum operations deleted from this table
tuples_frozen	int8	Number of tuples of this table that vacuum operations marked as frozen
dead_tuples	int8	Number of dead tuples vacuum operations left in this table due to their visibility in transactions
index_vacuum_count	int8	Number of times indexes on this table were vacuumed
rev_all_frozen_pages	int8	Number of times the all-frozen mark in the visibility map was removed for pages of this table
rev_all_visible_pages	int8	Number of times the all-visible mark in the visibility map was removed for pages of this table
wal_records	int8	Total number of WAL records generated by vacuum operations performed on this table
wal_fpi	int8	Total number of WAL full page images generated by vacuum operations performed on this table
wal_bytes	numeric	Total amount of WAL bytes generated by vacuum operations performed on this table
blk_read_time	float8	Time spent reading database blocks by vacuum operations performed on this table, in milliseconds (if track_io_timing is enabled, otherwise zero)
blk_write_time	float8	Time spent writing database blocks by vacuum operations performed on this table, in milliseconds (if track_io_timing is enabled, otherwise zero)

Postgres Pro Modules
and Extensions Shipped
as Individual Packages

Column	Type	Description
delay_time	float8	Time spent sleeping in a vacuum delay point by vacuum operations performed on this table, in milliseconds (see Section 18.4.4 for details)
system_time	float8	System CPU time of vacuuming this table, in milliseconds
user_time	float8	User CPU time of vacuuming this table, in milliseconds
total_time	float8	Total time of vacuuming this table, in milliseconds
interrupts	integer	Number of times vacuum operations performed on this table were interrupted on any errors

Columns `total_*`, `wal_*` and `blk_*` include data on vacuuming indexes on this table, while columns `system_time` and `user_time` only include data on vacuuming the heap.

G.2.4.8. The `pgpro_stats_vacuum_indexes` View

Important

Starting with Postgres Pro 16, this view contains no data because the statistics to be displayed are available through the catalog view `pg_stats_vacuum_indexes` (see [System Views](#) for details).

The `pgpro_stats_vacuum_indexes` view will contain one row for each index in the current database (including TOAST table indexes), showing statistics about vacuuming that specific index. These statistics are collected by the core system as explained in [Section 26.2](#). The table below describes the columns of the view.

Table G.79. `pgpro_stats_vacuum_indexes` Columns

Column	Type	Description
relid	oid	OID of an index
schema	name	Name of the schema this index is in
relname	name	Name of this index
total_blks_read	int8	Number of database blocks read by vacuum operations performed on this index
total_blks_hit	int8	Number of times database blocks were found in the buffer cache by vacuum operations performed on this index
total_blks_dirtied	int8	Number of database blocks dirtied by vacuum operations performed on this index
total_blks_written	int8	Number of database blocks written by vacuum operations performed on this index
rel_blks_read	int8	Number of blocks vacuum operations read from this index

Postgres Pro Modules
and Extensions Shipped
as Individual Packages

Column	Type	Description
rel_blks_hit	int8	Number of times blocks of this index were already found in the buffer cache by vacuum operations, so that a read was not necessary (this only includes hits in the Postgres Pro buffer cache, not the operating system's file system cache)
pages_deleted	int8	Number of pages deleted by vacuum operations performed on this index
tuples_deleted	int8	Number of dead tuples vacuum operations deleted from this index
wal_records	int8	Total number of WAL records generated by vacuum operations performed on this index
wal_fpi	int8	Total number of WAL full page images generated by vacuum operations performed on this index
wal_bytes	numeric	Total amount of WAL bytes generated by vacuum operations performed on this index
blk_read_time	float8	Time spent reading database blocks by vacuum operations performed on this index, in milliseconds (if track_io_timing is enabled, otherwise zero)
blk_write_time	float8	Time spent writing database blocks by vacuum operations performed on this index, in milliseconds (if track_io_timing is enabled, otherwise zero)
delay_time	float8	Time spent sleeping in a vacuum delay point by vacuum operations performed on this index, in milliseconds (see Section 18.4.4 for details)
system_time	float8	System CPU time of vacuuming this index, in milliseconds
user_time	float8	User CPU time of vacuuming this index, in milliseconds
total_time	float8	Total time of vacuuming this index, in milliseconds
interrupts	integer	Number of times vacuum operations performed on this index were interrupted on any errors

G.2.5. Data Types

G.2.5.1. The `pgpro_stats_rusage` Type

`pgpro_stats_rusage` is a record type that contains resource usage statistics of statement planning/execution. The fields of this type are shown in [Table G.80](#).

Table G.80. `pgpro_stats_rusage` Fields

Name	Type	Description
<code>reads</code>	<code>bigint</code>	Number of bytes read by the filesystem layer
<code>writes</code>	<code>bigint</code>	Number of bytes written by the filesystem layer
<code>user_time</code>	<code>double precision</code>	User CPU time used
<code>system_time</code>	<code>double precision</code>	System CPU time used
<code>minflts</code>	<code>bigint</code>	Number of page reclaims (soft page faults)
<code>majflts</code>	<code>bigint</code>	Number of page faults (hard page faults)
<code>nswaps</code>	<code>bigint</code>	Number of swaps
<code>msgsnds</code>	<code>bigint</code>	Number of IPC messages sent
<code>msgrcv</code>	<code>bigint</code>	Number of IPC messages received
<code>nsignals</code>	<code>bigint</code>	Number of signals received
<code>nvcsws</code>	<code>bigint</code>	Number of voluntary context switches
<code>nivcsws</code>	<code>bigint</code>	Number of involuntary context switches

G.2.6. Functions

`pgpro_stats_statements_reset(userid Oid, dbid Oid, queryid bigint, planid bigint, minmax_only boolean)` returns timestamp with time zone

`pgpro_stats_statements_reset` discards statistics gathered so far by `pgpro_stats` corresponding to the specified `userid`, `dbid`, `queryid`, and `planid`. If any of the parameters are not specified, the default value 0 (invalid) is used for each of them and the statistics that match with other parameters will be reset. If no parameter is specified or all the specified parameters are 0 (invalid), it will discard all statistics. If all statistics in the `pgpro_stats_statements` view are discarded, it will also reset the statistics in the `pgpro_stats_info` view. When `minmax_only` is `true` only the values of minimum and maximum planning and execution time will be reset (i.e. `min_plan_time`, `max_plan_time`, `min_exec_time` and `max_exec_time` fields). The default value for `minmax_only` parameter is `false`. Time of last min/max reset performed is shown in `minmax_stats_since` field of the `pgpro_stats_statements` view. This function returns the time of a reset. This time is saved to `stats_reset` field of `pgpro_stats_info` view or to `minmax_stats_since` field of the `pgpro_stats_statements` view if the corresponding reset was actually performed. By default, this function can only be executed by superusers. Access may be granted to others using `GRANT`.

Note

As statistics in the `pgpro_stats_vacuum_database`, `pgpro_stats_vacuum_tables`, and `pgpro_stats_vacuum_indexes` views are collected by the core system, to reset them, call the `pg_stat_reset()` function (see [Section 26.2.25](#) for details).

`pgpro_stats_statements(showtext boolean)` returns setof record

The `pgpro_stats_statements` view is defined in terms of a function also named `pgpro_stats_statements`. Users can also call the `pgpro_stats_statements` function directly, and by specifying `showtext := false` make query text be omitted (that is, the `OUT` argument that corresponds to the view's `query` column will return nulls). This feature is intended to support external tools that might wish to avoid the overhead of repeatedly retrieving query texts of indeterminate length. Such tools can instead cache the first query text observed for each entry themselves, since that is all `pgpro_stats` itself does, and then retrieve query texts only as needed. Since the server stores query texts in a file, this approach may reduce physical I/O for repeated examination of the `pgpro_stats_statements` data.

`pgpro_stats_info()` returns record

`pgpro_stats_info` view is defined in terms of a function also named `pgpro_stats_info`. Users can also call the `pgpro_stats_info` function directly.

`pgpro_stats_totals_reset(type text, id bigint)` returns timestamp with timezone

`pgpro_stats_totals_reset` discards statistics gathered so far by `pgpro_stats` corresponding to the specified object `type` and `id`. If no parameter is specified or the `type` parameter is set to 0, all statistics will be discarded. If `type` is set to a valid object type, then if `id` is specified, then statistics will be discarded only for the specified object, else, statistics will be discarded for all objects of the specified type. Otherwise, no statistics will be discarded. This function returns the time of a reset. By default, this function can only be executed by superusers. Access may be granted to others using `GRANT`.

`pgpro_stats_totals()` returns setof record

The `pgpro_stats_totals` view is defined in terms of a function also named `pgpro_stats_totals`. Users can also call the `pgpro_stats_totals` function directly.

`pgpro_stats_metrics()` returns setof record

Defines the `pgpro_stats_metrics` view, which is described in detail in [Table G.75](#).

`pgpro_stats_get_archiver()` returns setof record

Defines the `pgpro_stats_archiver` view, which is described in detail in [Table G.76](#).

`pgpro_stats_wal_sender_crc_errors()` returns bigint

In Postgres Pro Enterprise, returns the number of errors detected by the WAL sender process when the `wal_sender_check_crc` parameter is on. In Postgres Pro Standard, returns zero. Note that this counter is reset to zero when the cluster restarts.

`pgpro_stats_vacuum_database(dboid oid)` returns setof record

Defines the row of the `pgpro_stats_vacuum_database` view, which is described in detail in [Table G.77](#), for the database specified by `dboid`.

`pgpro_stats_vacuum_tables(dboid oid, relid oid)` returns setof record

Defines the row of the `pgpro_stats_vacuum_tables` view, which is described in detail in [Table G.78](#), for the database specified by `dboid` and table specified by `relid`. If `relid = 0`, the statistics for each table in the specified database are returned.

`pgpro_stats_vacuum_indexes(dboid oid, relid oid)` returns setof record

Defines the row of the `pgpro_stats_vacuum_indexes` view, which is described in detail in [Table G.79](#), for the database specified by `dboid` and index specified by `relid`. If `relid = 0`, the statistics for each index in the specified database are returned.

G.2.6.1. Functions for Creating Views that Emulate Other Extensions

`pgpro_stats` can create views similar to those available in [pg_stat_statements](#) and [pg_stat_kcache](#) extensions. Specifically, [pg_stat_statements](#), `pg_stat_statements_info`, `pg_stat_kcache` and `pg_stat_kcache_detail` views can be created. Each view is only created in a Postgres Pro version if it is available in `pg_stat_statements/pg_stat_kcache` extension for the same version of Postgres Pro/PostgreSQL. For example, the `pg_stat_statements_info` view is only created in Postgres Pro versions starting with 14. The following functions enable creating these views:

`pgpro_stats_create_pg_stat_statements_compatible_views()` returns void

Creates `pg_stat_statements` and `pg_stat_statements_info` views.

`pgpro_stats_create_pg_stat_kcache_compatible_views()` returns void

Creates `pg_stat_kcache` and `pg_stat_kcache_detail` views.

By default, these functions can only be executed by superusers. Access may be granted to others using `GRANT`.

To create `pg_stat_statements*` views, drop the `pg_stat_statements` extension if it was previously installed and call the function:

```
select pgpro_stats_create_pg_stat_statements_compatible_views();
```

To create `pg_stat_kcache*` views, drop the `pg_stat_kcache` extension if it was previously installed and call the function:

```
select pgpro_stats_create_pg_stat_kcache_compatible_views();
```

Once the views are created, you can work with them as if the `pg_stat_statements/pg_stat_kcache` extension is installed.

If you need to remove the views created earlier, do it in a regular way:

```
drop view pg_stat_statements;  
drop view pg_stat_statements_info;  
drop view pg_stat_kcache;  
drop view pg_stat_kcache_detail;
```

G.2.7. Configuration Parameters

G.2.7.1. General Settings

`pgpro_stats.max` (integer)

`pgpro_stats` only collects statistics about most frequent queries. The less frequently a query appears during the server operation, the less probable its inclusion in the statistics. Rare queries are almost immediately evicted from the statistics by more frequent queries. The `pgpro_stats.max` parameter defines the maximum number of unique pairs (normalized query text, normalized plan text) tracked by the module, (i.e., the maximum number of rows in the [pgpro_stats_statements](#) view). The larger this value, the larger the number of queries for which the information is stored. But this is achieved at the cost of reduced server performance when waiting for locks trying to access the statistics table in the shared memory and when periodically collecting garbage in the file with texts of queries and plans. The default value is 5000. This parameter can only be set at server start.

`pgpro_stats.max_totals` (integer)

`pgpro_stats.max_totals` is the maximum number of objects tracked by the module (i.e., the maximum number of rows in the `pgpro_stats_totals` view). If more distinct objects than that are observed, information about least-used objects is discarded. The default value is 1000. This parameter can only be set at server start.

`pgpro_stats.track` (enum)

`pgpro_stats.track` controls which statements are counted by the module. Specify `top` to track top-level statements (those issued directly by clients), `all` to also track nested statements (such as statements invoked within functions) with nesting level not greater than 100, or `none` to disable statement statistics collection. The default value is `top`. Only superusers can change this setting.

`pgpro_stats.track_utility` (boolean)

`pgpro_stats.track_utility` controls whether utility commands are tracked by the module. Utility commands are all those other than `SELECT`, `INSERT`, `UPDATE` and `DELETE`. The default value is `on`. Only superusers can change this setting.

`pgpro_stats.track_planning` (boolean)

`pgpro_stats.track_planning` controls whether planning operations and duration are tracked by the module. Enabling this parameter may incur a noticeable performance penalty, especially when statements with identical query structure are executed by many concurrent connections which compete to update a small number of `pgpro_stats_statements` entries. The default value is `off`. Only superusers can change this setting.

`pgpro_stats.track_totals` (boolean)

`pgpro_stats.track_totals` controls whether aggregate statistics for objects (cluster, users, databases etc.) are tracked by the module. The default value is `on`. Only superusers can change this setting.

`pgpro_stats.track_cluster` (boolean)

`pgpro_stats.track_cluster` controls whether aggregate statistics for the cluster are tracked by the module. The default value is `on`. Only superusers can change this setting.

`pgpro_stats.track_databases` (boolean)

`pgpro_stats.track_databases` controls whether aggregate statistics for the databases are tracked by the module. The default value is `on`. Only superusers can change this setting.

`pgpro_stats.track_users` (boolean)

`pgpro_stats.track_users` controls whether aggregate statistics for the users are tracked by the module. The default value is `on`. Only superusers can change this setting.

`pgpro_stats.track_applications` (boolean)

`pgpro_stats.track_applications` controls whether aggregate statistics for the applications (whose names are set by [application_name](#)) are tracked by the module. The default value is `on`. Only superusers can change this setting.

`pgpro_stats.track_client_addr` (boolean)

`pgpro_stats.track_client_addr` controls whether aggregate statistics for the client IP addresses are tracked by the module. The default value is `on`. Only superusers can change this setting.

`pgpro_stats.track_backends` (boolean)

`pgpro_stats.track_backends` controls whether aggregate statistics for the backends are tracked by the module. The default value is `on`. Only superusers can change this setting.

`pgpro_stats.save (boolean)`

`pgpro_stats.save` specifies whether to save statement statistics across server shutdowns. If it is off then statistics are neither saved at shutdown nor reloaded at server start. The default value is on. This parameter can only be set in the `postgresql.conf` file or on the server command line.

`pgpro_stats.plan_format (text)`

`pgpro_stats.plan_format` selects the EXPLAIN format for the query plan. Possible values are `text`, `xml`, `json`, and `yaml`. The default value is `text`. Changing this parameter requires a server restart.

`pgpro_stats.enable_profile (boolean)`

`pgpro_stats.enable_profile` enables sampling of wait events for separate statements. The default value is `true`. Changing this parameter requires a server restart.

`pgpro_stats.query_sample_rate (float)`

As `pgpro_stats` only collects statistics about most frequent queries, and rare queries are not included in the statistics, you can reduce the effect of the statistics collection on the server performance. This is possible because some time later than the statistics collection starts, almost all the statistics collected by the module will contain queries that are not very infrequent, and the set of types of the collected queries will not further change much if the value of `pgpro_stats.max` is sufficient and the average frequency for most of the frequent queries has no significant changes with the periods larger than the observation time. Such a stationary distribution of collected queries can also be achieved by increasing the time of the statistics collection, for example, twice, but only adding each second query to the statistics instead of every query, or considering each query, but adding queries to the statistics randomly, with a given probability. In this example, it equals 0.5. This allows you to considerably reduce the server load at the cost of increasing the time of the statistics collection. `pgpro_stats.query_sample_rate` is the parameter to implement this approach. For example: if `pgpro_stats.query_sample_rate` is set to 0.2 (1/5), in five hours of the server operation under the above conditions, the statistics will be collected that is similar to the statistics collected with `pgpro_stats.query_sample_rate = 1` in an hour.

You can set up `pgpro_stats.query_sample_rate` by experiment. Choose the observation time depending on the environment of the server operation, for example: one hour. Look at the collected statistics an hour after the start and then an hour later without resetting the statistics. If the main difference appears to be in the increased number of collected queries (`calls`) rather than in the type of the queries, you can safely reduce `pgpro_stats.query_sample_rate` twice. In the case of a considerable difference in the types of the collected queries, increase the observation time and/or the `pgpro_stats.max` parameter.

The default value is 1.0. Changing this parameter requires a server restart.

`pgpro_stats.profile_period (integer)`

`pgpro_stats.profile_period` specifies the period, in milliseconds, during which to sample wait events. The default value is 10. Only superusers can change this setting.

`pgpro_stats.metrics_buffer_size (integer)`

`pgpro_stats.metrics_buffer_size` specifies the size of the ring buffer used for collecting statistical metrics. The default value is 16kB. Changing this parameter requires a server restart.

`pgpro_stats.metrics_workers (integer)`

`pgpro_stats.metrics_workers` specifies the number of workers used to collect statistical metrics. If this parameter is set to 2 or higher, one of the workers serves as the primary worker distributing queries to other workers. If only one worker is available, it gets reloaded to connect to different databases. Setting this parameter to 0 disables metrics collection. The default value is 2. Changing this parameter requires a server restart.

`pgpro_stats.stats_temp_directory` (string)

`pgpro_stats.stats_temp_directory` specifies the directory with the external file to store query texts. This can be a path relative to the data directory or an absolute path. Changing this parameter requires a server restart.

G.2.7.2. Metrics Settings

The following parameters can be used to define a custom metric to collect. The *N* placeholder in the parameter name serves as a unique identifier of the metric to which this setting should apply; it must be set to a non-negative integer for each metric.

When you add these parameters for a new metric, you have to restart the server for the changes to take effect. Once the new metric is added, its parameters can be changed without a server restart by simply reloading the `postgresql.conf` configuration file.

`pgpro_stats.metric_N_name` (text)

The name of metric *N*. This name will be displayed in the `metric_name` column of the `pgpro_stats_metrics` view.

`pgpro_stats.metric_N_query` (text)

The query statement that defines the metric to collect.

`pgpro_stats.metric_N_period` (integer)

The time interval at which to collect metric *N*, in milliseconds. Default: 60000 ms

`pgpro_stats.metric_N_db` (text)

The list of databases for which to collect metric *N*. Database names must be separated by commas. You can specify the `*` character to select all databases in the cluster except the template databases. If you need to analyze the template databases as well, you have to specify them explicitly.

`pgpro_stats.metric_N_user` (text)

The name of the user on behalf of which to collect metric *N*. This user must have access to the database for which the metric is collected.

G.2.8. Tracing of Application Sessions

In `pgpro_stats`, tracing of application sessions is implemented. It is based on filters, which trigger logging the execution of queries that match filtering conditions. Queries and their `EXPLAIN` output are logged in so-called *trace files* specified by the user or in the system log file (if the trace file is not specified). Filters are stored in a table located in the shared memory. The rows of this table represent filters, and the columns contain filtering conditions and `EXPLAIN` options to be used (see [EXPLAIN](#) for details). You should fill this table with filters to start tracing of queries.

Once a database administrator adds a filter in any session, all subsequent executions of queries that match the filter conditions will be traced by all sessions of the instance without a need in the server restart. In other words, filters can be added, deleted, or updated “on the fly”, and tracing with these filters immediately starts for existing and future sessions.

Note

Operations of adding, deleting, or updating filters are not transactional. Changes to the table of filters are not rolled back together with the transaction where these changes were made.

Columns of the table that stores filters are also called *filter attributes*. They are described in [Table G.81](#).

Table G.81. Filter Attributes

Name	Type	Description
filter_id	integer	Unique filter ID, which is automatically assigned to a filter when it is created, numbered from 1.
active	boolean	With the value of <code>false</code> , the filter is not active, which means that queries matching this filter are not logged. Default: <code>true</code> .
alias	name	Filter name, which can be specified for convenience. Only shown in the output of the <code>pgpro_stats_trace_show()</code> function. Default: empty string.
tracefile	name	Name of the trace file, where queries matching the filter and their <code>EXPLAIN</code> output are logged. If this filename is not specified, logging is done to the system log with the log level specified by <code>pgpro_stats.trace_log_level</code> . Trace files are created in <code>PGDATA/pg_stat</code> directory and have <code>trace</code> extension.
pid	integer	Process ID of the backend that executes the statement
database_name	name	Name of the database where the statement is executed
client_addr	name	IP address of the client connected to this backend
application_name	name	Name of the application that invoked execution of the statement
username	name	Name of the user who executes the statement
queryid	bigint	Internal hash code, computed from the statement's parse tree
planid	bigint	Internal hash code, computed from the statement's plan tree
duration	float8	Time spent in the planning and execution of the statement, in milliseconds
plan_time	float8	Time spent in the planning of the statement, in milliseconds
exec_time	float8	Time spent in the execution of the statement, in milliseconds
user_time	float8	User CPU time used in planning and execution of the statement
system_time	float8	System CPU time used in planning and execution of the statement

Postgres Pro Modules
and Extensions Shipped
as Individual Packages

Name	Type	Description
rows	int8	Total number of rows retrieved or affected by the statement
shared_blks_hit	int8	Total number of shared block cache hits by the statement
shared_blks_read	int8	Total number of shared blocks read by the statement
shared_blks_fetched	int8	Total number of shared blocks fetched from buffers by the statement
shared_blks_dirtied	int8	Total number of shared blocks dirtied by the statement
shared_blks_written	int8	Total number of shared blocks written by the statement
local_blks_hit	int8	Total number of local block cache hits by the statement
local_blks_read	int8	Total number of local blocks read by the statement
local_blks_fetched	int8	Total number of local blocks fetched from buffers by the statement
local_blks_dirtied	int8	Total number of local blocks dirtied by the statement
local_blks_written	int8	Total number of local blocks written by the statement
temp_blks_read	int8	Total number of temp blocks read by the statement
temp_blks_written	int8	Total number of temp blocks written by the statement
wal_bytes	numeric	Total amount of WAL bytes generated by the statement
total_wait_time	float8	Total time execution of this statement spent waiting
total_inval_msgs	bigint	Total number of cache invalidation messages generated by the statement (if this is supported by the server)
explain_analyze	boolean	If true, the <code>EXPLAIN</code> output will be logged with the <code>ANALYZE</code> option. By default, defined by the pgpro_stats.explain_analyze_default configuration parameter.
explain_verbose	boolean	If true, the <code>EXPLAIN</code> output will be logged with the <code>VERBOSE</code> option. By default, defined by the pgpro_stats.explain_verbose_default configuration parameter.
explain_costs	boolean	If true, the <code>EXPLAIN</code> output will be logged with the <code>COSTS</code> option. By default, defined by the pgpro_

Postgres Pro Modules
and Extensions Shipped
as Individual Packages

Name	Type	Description
		stats.explain_costs_default configuration parameter.
explain_settings	boolean	If true, the EXPLAIN output will be logged with the SETTINGS option. By default, defined by the pgpro_stats.explain_settings_default configuration parameter.
explain_buffers	boolean	If true, the EXPLAIN output will be logged with the BUFFERS option. By default, defined by the pgpro_stats.explain_buffers_default configuration parameter.
explain_wal	boolean	If true, the EXPLAIN output will be logged with the WAL option. By default, defined by the pgpro_stats.explain_wal_default configuration parameter.
explain_timing	boolean	If true, the EXPLAIN output will be logged with the TIMING option. By default, defined by the pgpro_stats.explain_timing_default configuration parameter.
explain_format	text	The value of the FORMAT option of EXPLAIN to be logged, which can be TEXT, XML, JSON, or YAML. By default, defined by the pgpro_stats.plan_format configuration parameter.
time_info	boolean	If true, includes additional information in the session-tracing output in the format defined by <code>explain_format : pid, duration</code> in milliseconds, start time — start time of the query execution, and stop time — end time of the query execution. See Example G.2 for details.

Filter attributes can be divided into the following groups:

- Control attributes, from `filter_id` to `tracefile` in [Table G.81](#).
- Identification attributes, from `pid` to `planid` in [Table G.81](#).
- Threshold attributes, from `duration` to `total_inval_msgs` in [Table G.81](#).
- Attributes that only control the output to the trace file or system log file and do not affect filtering. Most of them specify the EXPLAIN options. These are the attributes starting with `explain_analyze` up to the end of [Table G.81](#).

Query execution will be traced if both of these conditions are met:

- For all the specified identification attributes of the filter, the values of the respective characteristics of the query are the same as the values of these attributes.
- For all the specified threshold attributes of the filter, the values of the respective characteristics of the query are greater than or equal to the limits specified in these attributes.

It is allowed not to assign values to attributes. For all the attributes except `active`, you can also explicitly assign the value of `NULL`. If the value of a control attribute is undefined or it was explicitly set to `NULL`, this attribute will be assigned the default value shown in [Table G.81](#). For identification and threshold attributes, undefined or `NULL` values mean that queries will not be filtered by the respective characteristic. If no values are defined for all identification and all threshold attributes, all the queries are taken to be matching this filter and will be logged. If the attributes specifying `EXPLAIN` options are undefined, the default values defined by the configuration parameters will be used (see [Section G.2.8.2](#) for details).

Warning

Although when specifying a filter, you can assign values to any combination of filter attributes, bear in mind that a too general filter will lead to an excessive size of the trace file and will affect the performance more than desired as the main performance overhead is associated with writing to the trace file rather than with checking the filter conditions.

G.2.8.1. Session-Tracing Functions

Specialized functions enable creation, update and deletion of query filters:

`pgpro_stats_trace_insert(VARIADIC "any")` returns integer

Adds a filter to the list of session-tracing filters. A filter must be passed as a sequence of alternating key-value pairs, where the key is the name of the filter attribute from [Table G.81](#) except `filter_id`. For example:

```
pgpro_stats_trace_insert('pid', 42, 'database_name', 'main', 'explain_analyze',
true)
```

Key-value pairs are position-independent: they can be provided in any order, independently of the order of attributes in [Table G.81](#). Some of the attributes can be missing from the sequence. Such attributes will be assigned the default values. Returns the unique `filter_id`, which the function assigns to the added filter.

`pgpro_stats_trace_update(filter_id integer, VARIADIC "any")` returns boolean

Updates a session-tracing filter defined by `filter_id`. Filter attributes to update must be passed as a sequence of alternating key-value pairs, where the key is the name of the filter attribute from [Table G.81](#) except `filter_id`. Key-value pairs are position-independent: they can be provided in any order, independently of the order of attributes in [Table G.81](#). Filter attributes whose values are not explicitly specified will not be changed. The value of `NULL` for identification and threshold attributes resets the values of these attributes, which means that a query will match the conditions of the updated filter regardless of the respective characteristics. Returns `true` on success and `false` otherwise.

`pgpro_stats_trace_delete(filter_id integer)` returns boolean

Deletes a session-tracing filter defined by `filter_id`. Returns `true` on success and `false` otherwise.

`pgpro_stats_trace_reset()` returns integer

Removes all session-tracing filters. Returns the number of removed filters. By default, this function can only be executed by superusers. Access may be granted to others using `GRANT`.

`pgpro_stats_trace_show()` returns setof record

Displays the contents of the table of filters, whose columns are shown in [Table G.81](#).

G.2.8.2. Session-Tracing Configuration Parameters

The following parameters can be used to configure session-tracing logging. Note that `pgpro_stats.explain_*_default` settings define the logging behavior when the corresponding `explain_*` filter attributes (from [Table G.81](#)) are not specified or explicitly set to `NULL`.

`pgpro_stats.explain_analyze_default` (boolean)

If `true`, the `EXPLAIN` output will be logged with the `ANALYZE` option and without it if `false`. The default value is `false`. Only superusers can change this setting.

`pgpro_stats.explain_verbose_default` (boolean)

If `true`, the `EXPLAIN` output will be logged with the `VERBOSE` option and without it if `false`. The default value is `false`. Only superusers can change this setting.

`pgpro_stats.explain_costs_default` (boolean)

If `true`, the `EXPLAIN` output will be logged with the `COSTS` option and without it if `false`. The default value is `true`. Only superusers can change this setting.

`pgpro_stats.explain_settings_default` (boolean)

If `true`, the `EXPLAIN` output will be logged with the `SETTINGS` option and without it if `false`. The default value is `false`. Only superusers can change this setting.

`pgpro_stats.explain_buffers_default` (boolean)

If `true`, the `EXPLAIN` output will be logged with the `BUFFERS` option and without it if `false`. The default value is `false`. Only superusers can change this setting.

`pgpro_stats.explain_wal_default` (boolean)

If `true`, the `EXPLAIN` output will be logged with the `WAL` option and without it if `false`. The default value is `false`. Only superusers can change this setting.

`pgpro_stats.explain_timing_default` (boolean)

If `true`, the `EXPLAIN` output will be logged with the `TIMING` option and without it if `false`. The default value is `true`. Only superusers can change this setting.

`pgpro_stats.trace_log_level` (enum)

Defines the log level at which the `EXPLAIN` output will be logged to the system log file (when the trace file is not specified). Valid values are `DEBUG5`, `DEBUG4`, `DEBUG3`, `DEBUG2`, `DEBUG1`, `INFO`, `NOTICE`, `WARNING`, and `LOG`. The default value is `LOG`.

`pgpro_stats.trace_query_text_size` (int)

Defines the maximum size of query texts in the session-tracing output, in kilobytes. If the size of the query text in kilobytes is larger, it is trimmed to the maximum size. If this parameter is not specified, the default value of zero is used, which means that the whole query texts are output.

G.2.8.3. Examples Related to Session Tracing

Example G.1. Usage of Session-Tracing Functions

Let's add the filter first:

```
SELECT pgpro_stats_trace_insert('alias', 'first', 'pid', pg_backend_pid(),  
    'explain_analyze', true);
```

Let's add the filter second and specify logging to the trace file `second_tf.trace`:

```
SELECT pgpro_stats_trace_insert('alias', 'second', 'database_name', current_database(),  
    'explain_costs', false, 'tracefile', 'second_tf');
```

You can view the table with filters as follows:

```
\x auto
```

Postgres Pro Modules
and Extensions Shipped
as Individual Packages

```
SELECT * from pgpro_stats_trace_show();
```

```
-[ RECORD 1 ]-----+-----
```

filter_id	1
active	t
alias	first
tracefile	
pid	243183
database_name

explain_analyze	f
explain_verbose	f
explain_costs	f
explain_settings	f
explain_buffers	f
explain_wal	f
explain_timing	f
explain_format	text
time_info	f

The following query matches the conditions of both filters, so it must be logged in the system log file and in the specified trace file:

```
SELECT 1 as result;
```

The following is the output to the system log file:

```
2023-04-18 04:52:53.242 MSK [63112] LOG:  Filter 1 triggered explain of the plan:
Query Text: SELECT 1 as result;
Result (cost=0.00..0.01 rows=1 width=4) (actual time=0.003..0.003 rows=1 loops=1)
```

And the following is the output to the `second_tf.trace` trace file:

```
Query Text: SELECT 1 as result;
Result
```

Let's delete the first filter:

```
SELECT pgpro_stats_trace_delete(1);
```

Let's also change `pid` to 2 for the second filter

```
SELECT pgpro_stats_trace_update(2, 'pid', 2);
```

When you execute the query

```
SELECT 2 as result;
```

it does not get logged to `second_tf.trace`.

Now let's remove all filters from the table:

```
SELECT pgpro_stats_trace_reset();
```

Example G.2. Session-Tracing Output with `time_info = true`

The following is an example of the session-tracing output in the JSON format when `time_info = true`:

```
{
```

```
"Pid": 123456,
"Duration ms": 0.094691,
"Start time": "2025-01-12 15:39:27.580447+03",
"Stop time": "2025-01-12 15:39:27.587802+03",
"Query Text": "SELECT 2 AS Result;",
"Plan": {
  "Node Type": "Result",
  "Parallel Aware": false,
  "Async Capable": false,
  "Startup Cost": 0.00,
  "Total Cost": 0.01,
  "Plan Rows": 1,
  "Plan Width": 4
}
}
```

G.2.9. Cache Invalidation Metrics

Among the rest, `pgpro_stats` can collect cache invalidation statistics. This section provides some background information needed to better understand related metrics.

Each backend has its local cache, which allows you to minimize accesses for meta information on tables, for example, to the system catalogs. If a backend changes the meta information, this information must be updated in other backends' caches. This is implemented by sending invalidation messages through a queue: the backend that changed the meta information on some object sends an appropriate message to the queue.

All backends get invalidation messages from the queue. Depending on whether the object for which the invalidation message was received is cached, the backend either ignores the message (when the object is not cached) or updates its cache (when the object is cached). In `pgpro_stats`, most invalidation message counters, unless explicitly stated otherwise for certain counters, are incremented when backends just generate messages, which will only be sent to the queue upon commit of the appropriate transaction. Note that the counters will remain incremented if the transaction is rolled back, although the message will not be sent to the queue.

When a backend that is adding messages to the queue figures out that the queue size reached a certain limit, it starts a cleanup by deleting messages already processed by all backends, and if backends are found that heavily fall behind and thus delay the cleanup, they get a reset signal, which forces them to reset all their caches.

G.2.9.1. The `pgpro_stats_inval_status` View

The `pgpro_stats_inval_status` view shows one row with the current status of the cache invalidation global queue. The columns of the view are shown in [Table G.82](#).

Table G.82. `pgpro_stats_inval_status` Columns

Name	Type	Description
<code>num_inval_messages</code>	<code>int8</code>	Current number of invalidation messages in the queue
<code>num_inval_queue_cleanups</code>	<code>int8</code>	Number of invalidation queue cleanups done to prevent its overflow
<code>num_inval_queue_resets</code>	<code>int4</code>	Number of cache resets for backends that fail to process messages fast enough

In a working system, `num_inval_messages` usually approximately equals 4000, which means that the queue is pretty full. The speed of the `num_inval_queue_cleanups` growth is determined by how fast in-

validation messages are generated. Growth of `num_inval_queue_resets` is normally zero, and non-zero growth indicates either too fast generation of messages or delays in processing messages by backends. Monitoring `num_inval_queue_cleanups` and `num_inval_queue_resets` may in some cases allow you to detect problematic backend/backends as described below.

If for a certain time interval, `num_inval_queue_cleanups` considerably increased, while `num_inval_queue_resets` did not, this indicates that invalidation messages are generated faster and/or backends process them more slowly, but backends still manage to process messages before the queue overflows.

If for a time interval, `num_inval_queue_cleanups` did not considerably increase, while `num_inval_queue_resets` did, this definitely indicates a delay in processing messages by backend(s), and the `cache_resets` column of the `pgpro_stats_totals` view allows you to figure out which backend(s) to blame.

If for a time interval, both counters considerably increased, this also indicates that invalidation messages are generated faster and/or backends process them more slowly, but this time backends fail to process messages before the queue overflows. The `cache_resets` column of the `pgpro_stats_totals` view allows you detect which backend(s) delay message processing. In this case, it is not possible to definitely conclude whether too fast generation of messages or a delay in message processing accounts for the growth of `num_inval_queue_resets`. However, the `totals` counter of the `pgpro_stats_inval_msgs` view may help here. If the change of this counter for that interval is pretty the same as for a previous interval of the same length, you can definitely conclude that the growth is caused by backend delays.

The `pgpro_stats_inval_status` view can be defined in terms of a function:

```
pgpro_stats_inval_status() returns record
```

Defines the `pgpro_stats_inval_status` view, which is described in detail in [Table G.82](#).

G.2.9.2. The `pgpro_stats_inval_msgs` Type

The `pgpro_stats_statements` and `pgpro_stats_totals` views for each corresponding object, show a record of the `pgpro_stats_inval_msgs` record type containing counters for cache invalidation messages. The fields of the type are shown in [Table G.83](#).

Table G.83. `pgpro_stats_inval_msgs` Fields

Name	Type	Description
<code>total</code>	<code>bigint</code>	Total number of invalidation messages
<code>catcache</code>	<code>bigint</code>	Number of selective catalog cache invalidation messages
<code>catalog</code>	<code>bigint</code>	Number of whole catalog cache invalidation messages
<code>relcache</code>	<code>bigint</code>	Number of selective relation cache invalidation messages
<code>relcache_all</code>	<code>bigint</code>	Number of whole relation cache invalidation messages
<code>smgr</code>	<code>bigint</code>	Number of invalidation messages of open relation files. Gets incremented when the messages are sent to the queue.
<code>relmap</code>	<code>bigint</code>	Number of relation map cache invalidation messages. Gets incremented when the messages are sent to the queue.

Postgres Pro Modules
and Extensions Shipped
as Individual Packages

Name	Type	Description
snapshot	bigint	Number of catalog snapshot in- validation messages

G.2.10. Authors

Postgres Professional, Moscow, Russia

Appendix H. Third-Party Modules and Extensions Shipped as Individual Packages

This appendix contains third-party modules and extensions that are made available in Postgres Pro Standard as individual packages. These packages are listed in [Section 16.1.4.1](#), and the documentation for each module explains which package to choose to install it. [Appendix F](#) and [Appendix G](#) cover more modules and extensions included in the Postgres Pro Standard distribution. Note also the following extensions that are shipped as individual packages: orafce, pgvector, pldebugger, and plv8 (see [Table 16.3](#) for details).

H.1. oracle_fdw — access to Oracle databases

The `oracle_fdw` module is a Postgres Pro extension that provides a Foreign Data Wrapper for easy and efficient access to Oracle databases, including pushdown of `WHERE` conditions and required columns as well as comprehensive `EXPLAIN` support.

H.1.1. Installation

The `oracle_fdw` extension is provided with Postgres Pro Standard as a separate pre-built package `oracle-fdw-std-16` (for the detailed installation instructions, see [Chapter 16](#)). `oracle_fdw` requires Oracle Instant Client version 19.5.

For RPM-based systems (RHEL, SUSE, Red OS, ROSA, ALT Linux), download the `oracle-instantclient` RPM and install it using `rpm`. If you use a Debian-based system (Ubuntu, Astra Linux), you have to either convert the RPM package to a Debian package using `alien`, and then install it using `dpkg`, or download the ZIP archive of the client and extract the contents of the archive into the `/opt/oracle` directory.

Once you have Postgres Pro Standard installed, create the `oracle_fdw` extension:

```
CREATE EXTENSION oracle_fdw;
```

That will define the required functions and create a foreign data wrapper.

Note that the extension version as shown by the `psql \dx` command or the system catalog `pg_available_extensions` is *not* the installed version of `oracle_fdw`. To get the `oracle_fdw` version, use the [oracle_diag](#) function.

H.1.2. Internals

`oracle_fdw` sets the `MODULE` of the Oracle session to `postgres` and the `ACTION` to the backend process number. This can help identifying the Oracle session and allows you to trace it with `DBMS_MONITOR.SERV_MOD_ACT_TRACE_ENABLE`.

`oracle_fdw` uses Oracle array interface to avoid unnecessary client-server round-trips. The batch size can be configured with the [prefetch](#) table option and is set to 50 by default.

Rather than using a `PLAN_TABLE` to explain an Oracle query (which would require such a table to be created in the Oracle database), `oracle_fdw` uses execution plans stored in the library cache. For that, an Oracle query is *explicitly described*, which forces Oracle to parse the query. The hard part is to find the `SQL_ID` and `CHILD_NUMBER` of the statement in `V$SQL` because the `SQL_TEXT` column contains only the first 1000 bytes of the query. Therefore, `oracle_fdw` adds a comment to the query that contains a hash of the query text. This is used to search in `V$SQL`. The actual execution plan or cost information is retrieved from `V$SQL_PLAN`.

`oracle_fdw` uses transaction isolation level `SERIALIZABLE` on the Oracle side, which corresponds to Postgres Pro's `REPEATABLE READ`. This is necessary because a single Postgres Pro statement can lead to multiple Oracle queries (e.g. during a nested loop join) and the results need to be consistent. Unfortunately, the Oracle implementation of `SERIALIZABLE` has certain quirks; see the [Problems](#) section for more.

The Oracle transaction is committed immediately before the local transaction commits, so that a completed Postgres Pro transaction guarantees that the Oracle transaction has completed. However, there is a small chance that the Postgres Pro transaction cannot complete even though the Oracle transaction is committed. This cannot be avoided without using two-phase transactions and a transaction manager, which is beyond what a foreign data wrapper can reasonably provide. Prepared statements involving Oracle are not supported for the same reason.

H.1.3. Short Simple Example

This is an example how to use `oracle_fdw`. More detailed information is provided in the sections [Options](#) and [Usage](#). You should also read the [documentation on foreign data](#) and the commands referenced there.

For the sake of this example, let's assume you can connect to Oracle as the operating system user `postgres` (or whoever starts the Postgres Pro server) with the following command:

```
sqlplus orauser/orapwd@//dbserver.mydomain.com:1521/ORADB
```

That means that the Oracle client and the environment are set up correctly. It is also assumed that `oracle_fdw` has been installed (see the [Installation](#) section).

We want to access a table defined like this:

```
SQL> DESCRIBE oratab
Name                               Null?    Type
-----
ID                                 NOT NULL NUMBER(5)
TEXT                               VARCHA2 (30)
FLOATING                           NOT NULL NUMBER(7,2)
```

Then configure `oracle_fdw` as a Postgres Pro superuser like this:

```
pgdb=# CREATE EXTENSION oracle_fdw;
pgdb=# CREATE SERVER oradb FOREIGN DATA WRAPPER oracle_fdw
      OPTIONS (dbserver '//dbserver.mydomain.com:1521/ORADB');
```

You can use other naming methods or local connections, see the description of [dbserver](#) below.

It is a good idea to use a superuser only where really necessary, so let's allow a normal user to use the foreign server (this is not required for the example to work but recommended):

```
pgdb=# GRANT USAGE ON FOREIGN SERVER oradb TO pguser;
```

Then you can connect to Postgres Pro as `pguser` and define the following:

```
pgdb=> CREATE USER MAPPING FOR pguser SERVER oradb
      OPTIONS (user 'orauser', password 'orapwd');
```

You can use external authentication to avoid storing Oracle passwords.

```
pgdb=> CREATE FOREIGN TABLE oratab (
    id          integer          OPTIONS (key 'true') NOT NULL,
    text        character varying(30),
    floating    double precision NOT NULL
) SERVER oradb OPTIONS (schema 'ORAUSER', table 'ORATAB');
```

Remember that the table and schema name (the latter is optional) must normally be in uppercase.

Now you can use the table like a regular Postgres Pro table.

H.1.4. Usage

H.1.4.1. Oracle Permissions

The Oracle user will need the `CREATE SESSION` privilege and the right to select from the table or view in question. Note that `oracle_fdw` accesses the Oracle table at query planning time to get its definition. This happens *before* permissions on the foreign table are checked. Consequently, you may receive an Oracle error if you try to access a foreign table on which you have no permissions in Postgres Pro. This is expected and no security problem.

For `EXPLAIN VERBOSE`, the user will also need `SELECT` privileges on `V$SQL` and `V$SQL_PLAN`.

H.1.4.2. Connections

`oracle_fdw` caches Oracle connections because it is expensive to create an Oracle session for each individual query. All connections are automatically closed when the Postgres Pro session ends.

The `close_connections` function can be used to close all cached Oracle connections. This can be useful for long-running sessions that do not access foreign tables all the time and want to avoid blocking the resources needed by an open Oracle connection. You cannot call this function inside a transaction that modifies Oracle data.

H.1.4.3. Columns

When you define a foreign table, the columns of the Oracle table are mapped to the Postgres Pro columns in the order of their definition.

`oracle_fdw` will only include those columns in the Oracle query that are actually needed by the Postgres Pro query.

The Postgres Pro table can have more or less columns than the Oracle table. If it has more columns, and these columns are used, you will receive a warning and `NULL` values will be returned.

If you want to `UPDATE` or `DELETE`, make sure that the `key` option is set on all columns that belong to the table's primary key. Failure to do so will result in errors.

H.1.4.4. Data Types

You must define the Postgres Pro columns with data types that `oracle_fdw` can translate (see the conversion table below). This restriction is only enforced if the column actually gets used, so you can define “dummy” columns for untranslatable data types as long as you don't access them (this trick only works with `SELECT`, not when modifying foreign data). If an Oracle value exceeds the size of the Postgres Pro column (e.g., the length of a `varchar` column or the maximal `integer` value), you will receive a runtime error.

These conversions are automatically handled by `oracle_fdw`:

Oracle type	Possible PostgreSQL types
CHAR	char, varchar, text
NCHAR	char, varchar, text
VARCHAR	char, varchar, text
VARCHAR2	char, varchar, text, json
NVARCHAR2	char, varchar, text
CLOB	char, varchar, text, json
LONG	char, varchar, text
RAW	uuid, bytea
BLOB	bytea

BFILE	bytea (read-only)
LONG RAW	bytea
NUMBER	numeric, float4, float8, char, varchar, text
NUMBER(n,m) with m<=0	numeric, float4, float8, int2, int4, int8, boolean, char, varchar, text
FLOAT	numeric, float4, float8, char, varchar, text
BINARY_FLOAT	numeric, float4, float8, char, varchar, text
BINARY_DOUBLE	numeric, float4, float8, char, varchar, text
DATE	date, timestamp, timestamptz, char, varchar, text
TIMESTAMP	date, timestamp, timestamptz, char, varchar, text
TIMESTAMP WITH TIME ZONE	date, timestamp, timestamptz, char, varchar, text
TIMESTAMP WITH LOCAL TIME ZONE	date, timestamp, timestamptz, char, varchar, text
INTERVAL YEAR TO MONTH	interval, char, varchar, text
INTERVAL DAY TO SECOND	interval, char, varchar, text
XMLTYPE	xml, char, varchar, text
MDSYS.SDO_GEOMETRY	geometry (see "PostGIS support" below)

If a NUMBER is converted to a boolean, 0 means false, everything else true.

Inserting or updating XMLTYPE only works with values that do not exceed the maximum length of the VARCHAR2 data type (4000 or 32767, depending on the MAX_STRING_SIZE parameter).

NCLOB is currently not supported because Oracle cannot automatically convert it to the client encoding.

If you want to convert TIMESTAMP WITH LOCAL TIME ZONE to timestamp, consider setting the set_time-zone option on the foreign server.

If you need conversions exceeding the above, define an appropriate view in Oracle or Postgres Pro.

H.1.4.5. WHERE Conditions and ORDER BY Clauses

Postgres Pro will use all applicable parts of the WHERE clause as a filter for the scan. The Oracle query that oracle_fdw constructs will contain a WHERE clause corresponding to these filter criteria whenever such a condition can safely be translated to Oracle SQL. This feature, also known as *push-down* of WHERE clauses, can greatly reduce the number of rows retrieved from Oracle and may enable Oracle's optimizer to choose a good plan for accessing the required tables.

Similarly, ORDER BY clauses will be pushed down to Oracle wherever possible. Note that no ORDER BY condition that sorts by a character string will be pushed down as the sort orders in Postgres Pro and Oracle cannot be guaranteed to be the same.

To make use of that, try to use simple conditions for the foreign table. Choose Postgres Pro column data types that correspond to Oracle's types because otherwise conditions cannot be translated.

The expressions now(), transaction_timestamp(), current_timestamp, current_date, and local-timestamp will be translated correctly.

The output of EXPLAIN will show the Oracle query used so you can see which conditions were translated to Oracle and how.

H.1.4.6. Joins Between Foreign Tables

oracle_fdw can push down joins to the Oracle server, that is, a join between two foreign tables will lead to a single Oracle query that performs the join on the Oracle side.

There are some restrictions when this can happen:

- Both tables must be defined on the same foreign server.
- Joins between three or more tables won't be pushed down.

- The join must be in a `SELECT` statement.
- `oracle_fdw` must be able to push down all join conditions and `WHERE` clauses.
- Cross joins without join conditions are not pushed down.
- If a join is pushed down, `ORDER BY` clauses will not be pushed down.

It is important that table statistics for both foreign tables have been collected with `ANALYZE` for Postgres Pro to determine the best join strategy.

H.1.4.7. Modifying Foreign Data

`oracle_fdw` supports `INSERT`, `UPDATE`, and `DELETE` on foreign tables. This is allowed by default (also in databases upgraded from an earlier Postgres Pro release) and can be disabled by setting the `readonly` table option.

For `UPDATE` and `DELETE` to work, the columns corresponding to the primary key columns of the Oracle table must have the `key` column option set. These columns are used to identify a foreign table row, so make sure that the option is set on *all* columns that belong to the primary key.

If you omit a foreign table column during `INSERT`, that column is set to the value defined in the `DEFAULT` clause on the Postgres Pro foreign table (or `NULL` if there is no `DEFAULT` clause). `DEFAULT` clauses on the corresponding Oracle columns are not used. If the Postgres Pro foreign table does not include all columns of the Oracle table, the Oracle `DEFAULT` clauses will be used for the columns not included in the foreign table definition.

The `RETURNING` clause on `INSERT`, `UPDATE` and `DELETE` is supported except for columns with Oracle data types `LONG` and `LONG RAW` (Oracle doesn't support these data types in the `RETURNING` clause).

Triggers on foreign tables are supported. Triggers defined with `AFTER` and `FOR EACH ROW` require that the foreign table has no columns with Oracle data type `LONG` or `LONG RAW`. This is because such triggers make use of the `RETURNING` clause mentioned above.

While modifying foreign data works, the performance is not particularly good, specifically when many rows are affected, because (owing to the way foreign data wrappers work) each row has to be treated individually.

Transactions are forwarded to Oracle so `BEGIN`, `COMMIT`, `ROLLBACK`, and `SAVEPOINT` work as expected. Prepared statements involving Oracle are not supported. See the [Internals](#) section for details.

Since `oracle_fdw` uses serialized transactions by default, it is possible that data modifying statements lead to a serialization failure:

```
ORA-08177: can't serialize access for this transaction
```

This can happen if concurrent transactions modify the table and gets more likely in long running transactions. Such errors can be identified by their `SQLSTATE` (40001). An application using `oracle_fdw` should retry transactions that fail with this error.

It is possible to use a different transaction isolation level, see [Foreign Server Options](#) for a discussion.

H.1.4.8. EXPLAIN

Postgres Pro's `EXPLAIN` will show the query that is actually issued to Oracle. `EXPLAIN VERBOSE` will show Oracle's execution plan (that will not work with Oracle server 9i or older, see [Problems](#)).

H.1.4.9. ANALYZE

You can use `ANALYZE` to gather statistics on a foreign table. This is supported by `oracle_fdw`.

Without statistics, Postgres Pro has no way to estimate the row count for queries on a foreign table, which can cause bad execution plans to be chosen.

Postgres Pro will *not* automatically gather statistics for foreign tables with the autovacuum daemon like it does for normal tables, so it is particularly important to run `ANALYZE` on foreign tables after creation and whenever the remote table has changed significantly.

Keep in mind that analyzing an Oracle foreign table will result in a full sequential table scan. You can use the table option `sample_percent` to speed this up by using only a sample of the Oracle table.

H.1.4.10. PostGIS Support

The data type `geometry` is only available when PostGIS is installed.

The only supported geometry types are `POINT`, `LINE`, `POLYGON`, `MULTIPOINT`, `MULTILINE`, and `MULTIPOLYGON` in two and three dimensions. Empty PostGIS geometries are not supported because they have no equivalent in Oracle Spatial.

NULL values for Oracle `SRID` will be converted to 0 and vice versa. For other conversions between Oracle `SRID` and PostGIS `SRID`, create a file `srid.map` in the Postgres Pro `share` directory. Each line of this file shall contain an Oracle `SRID` and the corresponding PostGIS `SRID`, separated by a whitespace. Keep the file small for good performance.

H.1.4.11. Support for `IMPORT FOREIGN SCHEMA`

`IMPORT FOREIGN SCHEMA` is supported to bulk import table definitions for all tables in an Oracle schema. In addition to the documentation of `IMPORT FOREIGN SCHEMA`, consider the following:

- `IMPORT FOREIGN SCHEMA` will create foreign tables for all objects found in `ALL_TAB_COLUMNS`. That includes tables, views and materialized views, but not synonyms.
- These are the supported options for `IMPORT FOREIGN SCHEMA`:
 - `case` controls case folding for table and column names during import.

The possible values are:

- `keep`: leave the names as they are in Oracle, usually in upper case.
- `lower`: translate all table and column names to lower case.
- `smart`: only translate names that are all upper case in Oracle (this is the default).
- `collation` is the collation used for case folding for the `lower` and `smart` options of `case`.

The default value is `default`, which is the database's default collation. Only collations in the `pg_catalog` schema are supported. See the `collname` values in the `pg_collation` catalog for a list of possible values.

- `dblink` is the Oracle database link through which the schema is accessed.

This name must be written exactly as it occurs in Oracle's system catalog so normally consist of uppercase letters only.

- `readonly` sets the `readonly` option on all imported tables.
- `skip_tables` (default `false`): don't import tables.
- `skip_views` (default `false`): don't import views.
- `skip_matviews` (default `false`): don't import materialized views.
- `max_long` sets the `max_long` option on all imported tables.
- `sample_percent` sets the `sample_percent` option on all imported tables.
- `prefetch` sets the `prefetch` option on all imported tables.
- `lob_prefetch` sets the `lob_prefetch` option on all imported tables.
- `nchar` sets the `nchar` option on all imported tables.

- `set_timezone` sets the [set_timezone](#) option on all imported tables.
- The Oracle schema name must be written exactly as it is in Oracle, so normally in upper case. Since Postgres Pro translates names to lower case before processing, you must protect the schema name with double quotes (for example, "SCOTT").
- Table names in the `LIMIT TO` or `EXCEPT` clause must be written as they will appear in Postgres Pro after the case folding described above.

Note that `IMPORT FOREIGN SCHEMA` does not work with Oracle server 8i; see the [Problems](#) section for details.

H.1.5. Reference

H.1.5.1. Objects Created by the Extension

```
oracle_fdw_handler() RETURNS fdw_handler
oracle_fdw_validator(text[], oid) RETURNS void
```

These functions are the handler and validator functions necessary to create a foreign data wrapper.

```
FOREIGN DATA WRAPPER oracle_fdw
  HANDLER oracle_fdw_handler
  VALIDATOR oracle_fdw_validator
```

The extension automatically creates a foreign data wrapper named `oracle_fdw`. Normally, that's all you need, and you can proceed to define foreign servers. You can create additional Oracle foreign data wrappers, for example, if you need to set the [nls_lang](#) option (you can alter the existing `oracle_fdw` wrapper, but all modifications will be lost after a dump/restore).

```
oracle_close_connections() RETURNS void
```

This function can be used to close all open Oracle connections in this session. See [Usage](#) for further description.

```
oracle_diag(name DEFAULT NULL) RETURNS text
```

This function is useful for diagnostic purposes only. It will return the versions of `oracle_fdw`, Postgres Pro server, and Oracle client. If called with no argument or `NULL`, it will additionally return the values of some environment variables used for establishing Oracle connections. If called with the name of a foreign server, it will additionally return the Oracle server version.

```
oracle_execute(server name, stmt text) RETURNS void
```

This function can be used to execute arbitrary SQL statements on the remote Oracle server. That will only work with statements that do not return results (typically DDL statements).

Be careful when using this function since it might disturb the transaction management of `oracle_fdw`. Remember that running a DDL statement in Oracle will issue an implicit `COMMIT`. You are best advised to use this function outside of multi-statement transactions.

H.1.5.2. Options

H.1.5.2.1. Foreign Data Wrapper Options

Important

If you modify the default foreign data wrapper `oracle_fdw`, any changes will be lost upon dump/restore. Create a new foreign data wrapper if you want the options to be persistent. The SQL script shipped with the software contains a `CREATE FOREIGN DATA WRAPPER` statement you can use.

[nls_lang]

Sets the `NLS_LANG` environment variable for Oracle to this value. `NLS_LANG` is in the form *language_territory.charset* (for example, `AMERICAN_AMERICA.AL32UTF8`). This must match your database encoding. When this value is not set, `oracle_fdw` will automatically do the right thing if it can and issue a warning if it cannot. Set this only if you know what you are doing. See the [Problems](#) section.

H.1.5.2.2. Foreign Server Options

dbserver

The Oracle database connection string for the remote database. This can be in any of the forms that Oracle supports as long as your Oracle client is configured accordingly. Set this to an empty string for local (`BEQUEATH`) connections.

[isolation_level]

The transaction isolation level to use at the Oracle database. The value can be `serializable`, `read_committed`, or `read_only`. The default is `serializable`.

Note that the Oracle table can be queried more than once during a single Postgres Pro statement (for example, during a nested loop join). To make sure that no inconsistencies caused by race conditions with concurrent transactions can occur, the transaction isolation level must guarantee read stability. This is only guaranteed with Oracle's `SERIALIZABLE` or `READ ONLY` isolation levels.

Unfortunately Oracle's implementation of `SERIALIZABLE` is rather bad and causes serialization errors (ORA-08177) in unexpected situations, like inserts into the table. Using `READ COMMITTED` transactions works around this problem, but *there is a risk of inconsistencies*. If you want to use it, check your execution plans if the foreign scan could be executed more than once.

[nchar]

Setting this option to `on` chooses a more expensive character conversion on the Oracle side. This is required if Oracle tables have `NCHAR` or `NVARCHAR2` columns that contain characters that cannot be represented in the Oracle database character set. The default is `off`.

Setting `nchar` to `on` has a noticeable performance impact, and it causes ORA-01461 errors with `UPDATE` statements that set strings over 2000 bytes (or 16383 if you have `MAX_STRING_SIZE = EXTENDED`). This error seems to be an Oracle bug.

[set_timezone]

Setting this option to `on` sets the Oracle session time zone to the current value of the Postgres Pro parameter `timezone` when the connection to Oracle is made. This is only useful if you plan to use Oracle columns of type `TIMESTAMP WITH LOCAL TIME ZONE` and want to translate them to `timestamp without time zone` in Postgres Pro. The default is `off`.

Note that if you change `timezone` after the Oracle connection has been established, `oracle_fdw` will not change the Oracle session time zone. You can call `oracle_close_connections()` `RETURNS void` in that case so that a new connection is opened the next time you access a foreign table.

If Oracle does not recognize the time zone, connections will fail with an error like “ORA-01882: timezone region not found”.

In that case, either use a different `timezone` or leave the option set to `off` and set the environment variable `ORA_SDTZ` to an appropriate value in the environment of the Postgres Pro server.

H.1.5.2.3. User Mapping Options

user

The Oracle user name for the session. Set this to an empty string for *external authentication* if you don't want to store Oracle credentials in the Postgres Pro database (one simple way is to use an *external password store*).

password

The password for the Oracle user.

H.1.5.2.4. Foreign Table Options

table

The Oracle table name. This name must be written exactly as it occurs in Oracle's system catalog so normally consist of uppercase letters only.

To define a foreign table based on an arbitrary Oracle query, set this option to the query enclosed in parentheses:

```
OPTIONS (table '(SELECT col FROM tab WHERE val = ''string''))
```

Do not set the [schema](#) option in this case. INSERT, UPDATE, and DELETE will work on foreign tables defined on simple queries; if you want to avoid that (or confusing Oracle error messages for more complicated queries), use the table option [readonly](#).

dblink

The Oracle database link through which the table is accessed. This name must be written exactly as it occurs in Oracle's system catalog so normally consist of uppercase letters only.

[schema]

The table's schema (or owner). Useful to access tables that do not belong to the connecting Oracle user. This name must be written exactly as it occurs in Oracle's system catalog so normally consist of uppercase letters only.

[max_long]

The maximal length of any LONG, LONG RAW, and XMLTYPE columns in the Oracle table. Possible values are integers between 1 and 1073741823 (the maximal size of a `bytea` in Postgres Pro). This amount of memory will be allocated at least twice so large values will consume a lot of memory. If [max_long](#) is less than the length of the longest value retrieved, you will receive the error message “ORA-01406: fetched column value was truncated”. The default is 32767.

[readonly]

INSERT, UPDATE, and DELETE are only allowed on tables where this option is not set to yes/on/true. The default is false.

[sample_percent]

This option only influences ANALYZE processing and can be useful to ANALYZE very large tables in a reasonable time.

The value must be between 0.000001 and 100 and defines the percentage of Oracle table blocks that will be randomly selected to calculate Postgres Pro table statistics. This is accomplished using the SAMPLE BLOCK (x) clause in Oracle. The default is 100.

ANALYZE will fail with ORA-00933 for tables defined with Oracle queries and may fail with ORA-01446 for tables defined with complex Oracle views.

[prefetch]

Sets the number of rows that will be fetched with a single round-trip between Postgres Pro and Oracle during a foreign table scan. The value must be between 1 and 1000, where a value of zero disables prefetching. The default is 50.

Higher values can speed up performance but will use more memory on the Postgres Pro server.

Note that there is no prefetching if the Oracle table contains columns of the type `MDSYS.SDO_GEOMETRY`.

[lob_prefetch]

Sets the number of bytes that are prefetched for `BLOB`, `CLOB`, and `BFILE` values. LOBs that exceed that size will require additional round trips between Postgres Pro and Oracle so setting this value bigger than the size of your typical LOB will be good for performance. Choosing bigger values for this option can allocate more memory on the server side but will boost performance for large LOBs. The default is 1048576.

H.1.5.2.5. Column Options

[key]

If set to `yes/on/true`, the corresponding column on the foreign Oracle table is considered a primary key column. For `UPDATE` and `DELETE` to work, you must set this option on all columns that belong to the table's primary key. The default is `false`.

[strip_zeros]

If set to `yes/on/true`, ASCII 0 characters will be removed from the string during transfer. Such characters are valid in Oracle but not in Postgres Pro so they will cause an error when read by `oracle_fdw`. This option only makes sense for `character`, `character varying`, and `text` columns. The default is `false`.

H.1.6. Problems

H.1.6.1. Encoding

Characters stored in an Oracle database that cannot be converted to the Postgres Pro database encoding will silently be replaced by replacement characters, typically a normal or inverted question mark, by Oracle. You will get no warning or error messages.

If you use a Postgres Pro database encoding that Oracle does not know (currently these are `EUC_CN`, `EUC_KR`, `LATIN10`, `MULE_INTERNAL`, `WIN874`, and `SQL_ASCII`), non-ASCII characters cannot be translated correctly. You will get a warning in this case, and the characters will be replaced by replacement characters as described above.

You can set the `nls_lang` option of the foreign data wrapper to force a certain Oracle encoding, but the resulting characters will most likely be incorrect and lead to Postgres Pro error messages. This is probably only useful for `SQL_ASCII` encoding if you know what you are doing.

H.1.6.2. Limited Functionality in Old Oracle Versions

The definition of the Oracle system catalogs `V$SQL` and `V$SQL_PLAN` has changed with Oracle 10.1. Using `EXPLAIN VERBOSE` with older Oracle server versions will result in errors like:

```
ERROR:  error describing query: OCISmtExecute failed to execute
        remote query for sql_id
DETAIL:  ORA-00904: "LAST_ACTIVE_TIME": invalid identifier
```

There is no plan to fix this, since Oracle 9i has been out of Extended Support since 2010 and the functionality is not essential.

`IMPORT FOREIGN SCHEMA` throws the following error with Oracle server 8i:

```
ERROR:  error importing foreign schema: OCISmtExecute failed to execute
        column query
DETAIL:  ORA-00904: invalid column name
```

This is because the view `ALL_TAB_COLUMNS` lacks the column `CHAR_LENGTH`, which was added in Oracle 9i.

H.1.6.3. LDAP Libraries

The Oracle client shared library comes with its own LDAP client implementation conforming to [RFC 1823](#) so these functions have the same names as OpenLDAP's. This will lead to a name collision when the Postgres Pro server was configured `--with-ldap`.

The name collision will not be detected because `oracle_fdw` is loaded at runtime, but trouble will happen if anybody calls an LDAP function. Typically, OpenLDAP is loaded first so if Oracle calls an LDAP function (for example, if you use *directory naming* name resolution), the backend will crash. This can lead to messages like the following (seen on Linux) in the Postgres Pro server log:

```
../../../../libraries/libldap/getentry.c:29: ldap_first_entry:  
Assertion `( (ld)->ld_options.ldo_valid == 0x2 )' failed.
```

Since Postgres Pro is built `--with-ldap`, it may work as long as you don't use any LDAP client functionality in Oracle. On some platforms, you can force Oracle's client shared library to be loaded before the Postgres Pro server is started (`LD_PRELOAD` on Linux). Then Oracle's LDAP functions should get used. In that case, Oracle may be able to use LDAP functionality, but using LDAP from Postgres Pro will crash the backend.

You cannot use LDAP functionality both in Postgres Pro and in Oracle.

H.1.6.4. Serialization Errors

In Oracle 11.2 or above, inserting the first row into a newly created Oracle table with `oracle_fdw` will lead to a serialization error.

This is because of an Oracle feature called *deferred segment creation*, which defers allocation of storage space for a new table until the first row is inserted. This causes a serialization failure with serializable transactions.

This is no serious problem; you can work around it by either ignoring that first error or creating the table with `SEGMENT CREATION IMMEDIATE`.

A much nastier problem is that concurrent inserts can sometimes cause serialization errors when an index page is split concurrently with a modifying serializable transaction.

Oracle claims that this is not a bug, and the suggested solution is to retry the transaction that got a serialization error.

H.1.6.5. Oracle Bugs

This is the list of Oracle bugs that affect or have affected `oracle_fdw` in the past.

Bug 2728408 can cause “ORA-8177 cannot serialize access for this transaction” even if no modification of remote data is attempted. It can occur with Oracle server 8.1.7.4 (install one-off patch 2728408) or Oracle server 9.2 (install Patch Set 9.2.0.4 or better).

Oracle client 21c is known not to work for `CLOB` columns (they appear empty). There is no ultimate proof that that is an Oracle bug, but other versions are working fine.

H.1.7. Authors

Laurenz Albe, with notable contributions from Vincent Mora of Oslandia and Tatsuro Yamada of the NTT OSS Center.

H.2. `tds_fdw` — connect to databases that use the TDS protocol

The `tds_fdw` module provides the foreign data wrapper `tds_fdw`, which can connect to databases that use the Tabular Data Stream (TDS) protocol, such as [Sybase](#) databases and [Microsoft SQL Server](#).

This foreign data wrapper requires a library that implements the DB-Library interface, such as FreeTDS. This has been tested with FreeTDS, but not the proprietary implementations of DB-Library.

H.2.1. Limitations

Unlike `WHERE` and column pushdowns, which are supported when `match_column_names` is enabled, `JOIN` pushdown or write operations are not supported.

H.2.2. Installing `tds_fdw`

`tds_fdw` is provided with Postgres Pro Standard as a separate pre-built package `tds-fdw` (for the detailed installation instructions, see [Chapter 16](#)).

Install the `tds_fdw` extension using [CREATE EXTENSION](#).

H.2.3. Configuring `tds_fdw`

H.2.3.1. Managing Character Sets/Encoding

Although many newer versions of the TDS protocol will only use USC-2 to communicate with the server, FreeTDS converts the UCS-2 to the client character set of your choice. To set the client character set, you can set `client charset` in `freetds.conf`. See [The `freetds.conf` File](#) and [Localization and TDS 7.0](#) for details.

You may need more configuring in case you get an error like this with Microsoft SQL Server when working with Unicode data:

```
NOTICE: DB-Library notice: Msg #: 4004, Msg state: 1, Msg: Unicode data in a Unicode-only
collation or ntext data cannot be sent to clients using DB-Library (such as ISQL) or ODBC
version 3.7 or earlier., Server: PILLIUM\SQLEXPRESS, Process: , Line: 1, Level: 16
```

```
ERROR: DB-Library error: DB #: 4004, DB Msg: General SQL Server error: Check messages
from the SQL Server, OS #: -1, OS Msg: (null), Level: 16
```

In this case, you may have to manually set `tds` version in `freetds.conf` to 7.0 or higher. See [The `freetds.conf` File](#) and [Choosing a TDS protocol version](#) for details.

H.2.3.2. Configuring Encrypted Connections to MSSQL

This needs to be configured at the `freetds.conf`. See [The `freetds.conf` File](#) and under `freetds.conf` settings, look for encryption.

H.2.4. Usage

To prepare for database access using `tds_fdw`:

1. Create a foreign server object, using [CREATE SERVER](#), to represent each database you want to connect to.
2. Create a user mapping, using [CREATE USER MAPPING](#), for each database user you want to allow to access each foreign server.
3. Create a foreign table, using [CREATE FOREIGN TABLE](#) or [IMPORT FOREIGN SCHEMA](#), for each table you want to access.

H.2.4.1. Creating a Foreign Server

To create a foreign server, execute the [CREATE SERVER](#) command providing the following options:

`servername`

The `servername`, address or hostname of the foreign server. This can be a DSN, as specified in `freetds.conf`. See [FreeTDS name lookup](#) for details. You can set this option to a comma-separated list of server names, then each server is tried until the first connection succeeds. This is useful for automatic failover to a secondary server.

Required: Yes

Default: 127.0.0.1

port

The port of the foreign server. Instead of providing a port here, it can be specified in `freetds.conf` (if `servername` is a DSN).

Required: No

database

The database to connect to for this server

Required: No

dbuse

If `dbuse` is 0, `tds_fdw` will connect directly to `database`. If `dbuse` is not 0, `tds_fdw` will connect to the server's default database and then select the database by calling the DB-Library's `dbuse()` function. For Azure, `dbuse` currently needs to be set to 0.

Required: No

Default: 0

language

The language to use for messages and the locale to use for date formats. FreeTDS may default to U.S. English on most systems. You can probably also change this in `freetds.conf`. For information related to this for MS SQL Server, see [SET LANGUAGE in MS SQL Server](#). For information related to Sybase ASE, see [Sybase ASE login options](#) and [SET LANGUAGE in Sybase ASE](#).

Required: No

character_set

The client character set to use for the connection if you need to set this for some reason. For TDS protocol versions 7.0+, the connection always uses UCS-2, so this parameter does nothing in those cases. See [Localization and TDS 7.0](#) for details.

Required: No

tds_version

The version of the TDS protocol to use for this server. See [Choosing a TDS protocol version](#) and [History of TDS Versions](#) for details.

Required: No

msg_handler

The function used for the TDS message handler. Can be one of the following values:

- `notice`: TDS messages are turned into PostgreSQL notices
- `blackhole`: TDS messages are ignored

Required: No

Default: `blackhole`

fdw_startup_cost

A cost that is used in query planning to represent the overhead of using this foreign data wrapper.

Required: No

`fdw_tuple_cost`

A cost that is used in query planning to represent the overhead of fetching rows from this server.

Required: No

`sqlserver_ansi_mode`

A cost that is used to represent the overhead of fetching rows from this server used in query planning.

This option is supported for SQL Server only. Setting this to `true` will enable the following server-side settings after a successful connection to the foreign server:

- `CONCAT_NULLS_YIELDS_NULL` ON
- `ANSI_NULLS` ON
- `ANSI_WARNINGS` ON
- `QUOTED_IDENTIFIER` ON
- `ANSI_PADDING` ON
- `ANSI_NULL_DFLT_ON` ON

Those parameters in summary are comparable to the SQL Server option `ANSI_DEFAULTS`. In contrast, `sqlserver_ansi_mode` currently does not activate the following options:

- `CURSOR_CLOSE_ON_COMMIT`
- `IMPLICIT_TRANSACTIONS`

This follows the behavior of the native ODBC and OLEDB driver for SQL servers, which explicitly turn them off if not configured otherwise.

Required: No

Default: `false`

Some foreign table options can also be set at the server level. Those include:

- `use_remote_estimate`
- `row_estimate_method`

Example H.1. Create a Foreign Server

```
CREATE SERVER mssql_svr
  FOREIGN DATA WRAPPER tds_fdw
  OPTIONS (servername '127.0.0.1', port '1433', database 'tds_fdw_test', tds_version
    '7.1');
```

H.2.4.2. Creating a User Mapping

To create a user mapping, execute the `CREATE USER MAPPING` command providing the following options:

`username`

The username of the account on the foreign server

Important

If you are using Azure SQL, then your username for the foreign server will need to be in the format `username@servername`. If you only use the username, the authentication will fail.

Required: Yes

password

The password of the account on the foreign server

Required: Yes

Example H.2. Create a User Mapping

```
CREATE USER MAPPING FOR postgres
SERVER mssql_svr
OPTIONS (username 'sa', password '');
```

H.2.4.3. Creating a Foreign Table

To create a foreign table, execute the [CREATE FOREIGN TABLE](#) command providing the following options:

query

The query string to use to query the foreign table

Required: Yes (mutually exclusive with [table_name](#))

schema_name

The schema that the table is in. The schema name can also be included in [table_name](#).

Required: No

table_name

The table on the foreign server to query

Aliases: *table*

Required: Yes (mutually exclusive with [query](#))

match_column_names

Match local columns with remote columns by comparing their table names instead of using the order in which they appear in the result set. Required for [WHERE](#) and column pushdowns.

Required: No

use_remote_estimate

Estimate the size of the table by performing some operation on the remote server, as defined by [row_estimate_method](#), instead of using the local estimate, as defined by [local_tuple_estimate](#)

Required: No

local_tuple_estimate

A locally set estimate of the number of tuples that is used when [use_remote_estimate](#) is disabled

Required: No

row_estimate_method

Can be one of the following values:

- `execute`: Execute the query on the remote server and get the actual number of rows in the query
- `showplan_all`: Get the estimated number of rows using *MS SQL Server's* `SET SHOWPLAN_ALL`

Required: No

Default: `execute`

Example H.3. Create a Foreign Table

Using a `table_name` definition:

```
CREATE FOREIGN TABLE mssql_table (  
    id integer,  
    data varchar)  
SERVER mssql_svr  
OPTIONS (table_name 'dbo.mytable', row_estimate_method 'showplan_all');
```

Using a `schema_name` and `table_name` definition:

```
CREATE FOREIGN TABLE mssql_table (  
    id integer,  
    data varchar)  
SERVER mssql_svr  
OPTIONS (schema_name 'dbo', table_name 'mytable', row_estimate_method  
'showplan_all');
```

Using a `query` definition:

```
CREATE FOREIGN TABLE mssql_table (  
    id integer,  
    data varchar)  
SERVER mssql_svr  
OPTIONS (query 'SELECT * FROM dbo.mytable', row_estimate_method 'showplan_all');
```

Setting a remote column name:

```
CREATE FOREIGN TABLE mssql_table (  
    id integer,  
    col2 varchar OPTIONS (column_name 'data'))  
SERVER mssql_svr  
OPTIONS (schema_name 'dbo', table_name 'mytable', row_estimate_method  
'showplan_all');
```

H.2.4.4. Importing a Foreign Schema

To import a foreign schema, execute the [IMPORT FOREIGN SCHEMA](#) command providing the following options:

`import_default`

Controls whether column `DEFAULT` expressions are included in the definitions of foreign tables

Required: No

Default: false

`import_not_null`

Controls whether column `NOT NULL` constraints are included in the definitions of foreign tables

Required: No

Default: true

Example H.4. Import a Foreign Schema

```
IMPORT FOREIGN SCHEMA dbo  
EXCEPT (mssql_table)  
FROM SERVER mssql_svr  
INTO public  
OPTIONS (import_default 'true');
```

H.2.4.5. Setting Variables

To set a variable, execute the [SET](#) command.

The following variables are available:

`tds_fdw.show_before_row_memory_stats`

Print memory context stats to the Postgres Pro log before each row is fetched

`tds_fdw.show_after_row_memory_stats`

Print memory context stats to the Postgres Pro log after each row is fetched

`tds_fdw.show_finished_memory_stats`

Print memory context stats to the Postgres Pro log when a query is finished

Example H.5. Set a Variable

```
postgres=# SET tds_fdw.show_finished_memory_stats=1;
SET
```

H.2.4.6. Viewing the Query Issued on the Remote System

To view the query issued on the remote system, execute the [EXPLAIN](#) [[VERBOSE](#)] command.

H.2.5. Author

Geoff Montee

H.3. wal2json — convert WAL changes into JSON via logical decoding

The `wal2json` module is a Postgres Pro extension for logical decoding that converts database changes from the write-ahead log (WAL) into `JSON` format. Postgres Pro has access to tuples generated by [INSERT](#) and [UPDATE](#) operations. Depending on the configured replica identity, it can also access previous row versions of `UPDATE` and `DELETE`. Changes can be consumed either through the streaming protocol (logical replication slots) or through a specialized SQL API.

Format version 1 generates a `JSON` object per transaction. This object contains all new and old tuples, with optional inclusion of properties such as transaction timestamps, schema-qualified names, data types, and transaction identifiers.

Format version 2 generates a `JSON` object per tuple, with optional `JSON` objects marking transaction start and end. Different tuple properties can also be included.

H.3.1. Installation and Setup

The `wal2json` extension is provided with Postgres Pro Standard as a separate pre-built package `wal2json-std-16` (for the detailed installation instructions, see [Chapter 16](#)). Once you have Postgres Pro Standard installed, complete the following steps to enable `wal2json`:

1. Enable logical decoding by setting `wal_level` to `logical` in the `postgresql.conf` file.

Optionally, you can also edit values of the `max_replication_slots` and `max_wal_senders` parameters.

2. Restart the database server for the changes to take effect.

H.3.2. Options

The `wal2json` module provides a variety of options for managing logical decoding:

`include-xids`

Add transaction IDs to each set of changes in the JSON output. The default is `off`.

`include-timestamp`

Add `timestamp` to each set of changes in the JSON output. The default is `off`.

`include-schemas`

Add the schema name to each change record in the JSON output. The default is `on`.

`include-types`

Add `type` to each change record in the JSON output. The default is `on`.

`include-typmod`

Add type modifiers for columns that have them. The default is `on`.

`include-type-oids`

Add type OIDs. The default is `off`.

`include-domain-data-type`

Replace a domain name with the underlying data type. The default is `off`.

`include-column-positions`

Add the column position (`pg_attribute.attnum`). The default is `off`.

`include-origin`

Add the origin of each change. The default is `off`.

`include-not-null`

Add information whether a column is marked as `not null` in the `columnoptionals` field of the JSON output. The default is `off`.

`include-default`

Add default expressions to the JSON output. The default is `off`.

`include-pk`

Add primary key information including column names and data type to the `pk` field of the JSON output. The default is `off`.

`numeric-data-types-as-string`

Convert values of numeric data types to strings in the JSON output. The JSON specification does not support `Infinity` and `NaN` as valid numeric values. There might be *potential interoperability problems* for double precision numbers. The default is `off`.

`pretty-print`

Add spaces and indentation to the JSON output structure. The default is `off`.

`write-in-chunks`

Enable writing the JSON output in smaller chunks instead of writing the entire changeset at once. This option is used only when `format-version` is set to 1. The default is `off`.

`include-lsn`

Add the `nextlsn` field to each changeset. The default is `off`.

`include-transaction`

Add records denoting the start and end of each transaction to the JSON output. The default is `off`.

`filter-origins`

Exclude changes from the specified origins. The default is empty, which means that no origin will be filtered. The value is a comma-separated list.

`filter-tables`

Exclude rows from the specified tables. The default is empty, which means that no table will be filtered. The value is a comma-separated list. The tables should be schema-qualified. `*.foo` means the `foo` table in all schemas, and `bar.*` means all tables in the `bar` schema. Special characters (space, single quote, comma, period, asterisk) must be escaped with backslash. Schema and table names are case-sensitive. For example, table `"public"."Foo bar"` should be specified as `public.Foo\ bar`.

`add-tables`

Include rows only from the specified tables. The default is empty, which means that all tables from all schemas are included. It follows the same rules as `filter-tables`.

`filter-msg-prefixes`

Exclude messages whose prefix is specified in the option value. The default is empty, which means that no messages will be filtered. The value is a comma-separated list.

`add-msg-prefixes`

Include only messages whose prefix is specified in the option value. The default is all prefixes. The value is a comma-separated list. `wal2json` applies `filter-msg-prefixes` before this option.

`format-version`

Define which output format to use. The default is 1.

`actions`

Define which operations will be included in the JSON output. The default is all actions (`INSERT`, `UPDATE`, `DELETE`, and `TRUNCATE`). However, if you are using `format-version = 1`, `TRUNCATE` is not enabled (for backward compatibility).

H.3.3. Examples

There are two ways to obtain the changes (JSON objects) from `wal2json`: [calling functions via SQL](#) or [pg_recvlogical](#).

H.3.3.1. `pg_recvlogical`

This is an example how to obtain JSON objects from `wal2json` using `pg_recvlogical`. Besides the configuration mentioned above, it is necessary to configure a replication connection to use `pg_recvlogical`. Since Postgres Pro version 10, logical replication matches a normal entry with a database name or keywords such as `all`.

To configure a replication connection and database parameters:

1. Add a replication connection rule to `pg_hba.conf`:

```
local    mydatabase    myuser                                trust
```

2. Optionally, set `max_wal_senders` in `postgresql.conf`:

```
max_wal_senders = 1
```

3. Restart the database server if you changed `max_wal_senders`.

To obtain JSON objects from `wal2json`:

1. Open a terminal and connect to the database:

```
$ pg_recvlogical -d postgres --slot test_slot --create-slot -P wal2json
$ pg_recvlogical -d postgres --slot test_slot --start -o pretty-print=1 -o
add-msg-prefixes=wal2json -f -
```

2. In another terminal:

```
$ cat /tmp/example1.sql
CREATE TABLE table1_with_pk (a SERIAL, b VARCHAR(30), c TIMESTAMP NOT NULL,
PRIMARY KEY(a, c));
CREATE TABLE table1_without_pk (a SERIAL, b NUMERIC(5,2), c TEXT);

BEGIN;
INSERT INTO table1_with_pk (b, c) VALUES('Backup and Restore', now());
INSERT INTO table1_with_pk (b, c) VALUES('Tuning', now());
INSERT INTO table1_with_pk (b, c) VALUES('Replication', now());
SELECT pg_logical_emit_message(true, 'wal2json', 'this message will be
delivered');
SELECT pg_logical_emit_message(true, 'pgoutput', 'this message will be
filtered');
DELETE FROM table1_with_pk WHERE a < 3;
SELECT pg_logical_emit_message(false, 'wal2json', 'this non-transactional
message will be delivered even if you rollback the transaction');

INSERT INTO table1_without_pk (b, c) VALUES(2.34, 'Tapir');
-- it is not added to stream because there isn't a pk or a replica identity
UPDATE table1_without_pk SET c = 'Anta' WHERE c = 'Tapir';
COMMIT;

DROP TABLE table1_with_pk;
DROP TABLE table1_without_pk;

$ psql -At -f /tmp/example1.sql postgres
CREATE TABLE
CREATE TABLE
BEGIN
INSERT 0 1
INSERT 0 1
INSERT 0 1
3/78BFC828
3/78BFC880
DELETE 2
3/78BFC990
INSERT 0 1
UPDATE 1
COMMIT
DROP TABLE
DROP TABLE
```

3. The output in the first terminal might look like this:

```
$ psql -At -f /tmp/example2.sql postgres
CREATE TABLE
CREATE TABLE
```

```
init
BEGIN
INSERT 0 1
INSERT 0 1
INSERT 0 1
3/78C2CA50
3/78C2CAA8
DELETE 2
3/78C2CBD8
INSERT 0 1
UPDATE 1
COMMIT

    "columntypes": ["integer", "numeric(5,2)", "text"],
    "columnvalues": [1, 2.34, "Tapir"]
}
]
}
stop
DROP TABLE
DROP TABLE
```

4. To drop the slot in the first terminal:

```
Ctrl+C
$ pg_recvlogical -d postgres --slot test_slot --drop-slot
```

H.3.3.2. Calling SQL Functions

These are examples how to obtain changes from wal2json via SQL.

If `format-version` is set to 1, the script might look like this:

```
$ cat /tmp/example2.sql
CREATE TABLE table2_with_pk (a SERIAL, b VARCHAR(30), c TIMESTAMP NOT NULL,
PRIMARY KEY(a, c));
CREATE TABLE table2_without_pk (a SERIAL, b NUMERIC(5,2), c TEXT);

SELECT 'init' FROM pg_create_logical_replication_slot('test_slot', 'wal2json');

BEGIN;
INSERT INTO table2_with_pk (b, c) VALUES('Backup and Restore', now());
INSERT INTO table2_with_pk (b, c) VALUES('Tuning', now());
```

```
INSERT INTO table2_with_pk (b, c) VALUES('Replication', now());
SELECT pg_logical_emit_message(true, 'wal2json', 'this message will be
delivered');
SELECT pg_logical_emit_message(true, 'pgoutput', 'this message will be
filtered');
DELETE FROM table2_with_pk WHERE a < 3;
SELECT pg_logical_emit_message(false, 'wal2json', 'this non-transactional
message will be delivered even if you rollback the transaction');

INSERT INTO table2_without_pk (b, c) VALUES(2.34, 'Tapir');
-- it is not added to stream because there isn't a pk or a replica identity
UPDATE table2_without_pk SET c = 'Anta' WHERE c = 'Tapir';
COMMIT;

SELECT data FROM pg_logical_slot_get_changes('test_slot', NULL, NULL, 'pretty-
print', '1', 'add-msg-prefixes', 'wal2json');
SELECT 'stop' FROM pg_drop_replication_slot('test_slot');

DROP TABLE table2_with_pk;
DROP TABLE table2_without_pk;
```

The expected output might look like this:

```
$ psql -At -f /tmp/example2.sql postgres
CREATE TABLE
CREATE TABLE
init
BEGIN
INSERT 0 1
INSERT 0 1
INSERT 0 1
3/78C2CA50
3/78C2CAA8
DELETE 2
3/78C2CBD8
INSERT 0 1
UPDATE 1
COMMIT
{
  "change": [
    {
      "kind": "message",
      "transactional": false,
      "prefix": "wal2json",
      "content": "this non-transactional message will be delivered even
if you rollback the transaction"
    }
  ]
}
psql:/tmp/example2.sql:17: WARNING:  table "table2_without_pk" without primary
key or replica identity is nothing
{
  "change": [
    {
      "kind": "insert",
      "schema": "public",
      "table": "table2_with_pk",
```

```
        "columnnames": ["a", "b", "c"],
        "columntypes": ["integer", "character varying(30)", "timestamp without
time zone"],
        "columnvalues": [1, "Backup and Restore", "2018-03-27 12:05:29.914496"]
    },
    {
        "kind": "insert",
        "schema": "public",
        "table": "table2_with_pk",
        "columnnames": ["a", "b", "c"],
        "columntypes": ["integer", "character varying(30)", "timestamp without
time zone"],
        "columnvalues": [2, "Tuning", "2018-03-27 12:05:29.914496"]
    },
    {
        "kind": "insert",
        "schema": "public",
        "table": "table2_with_pk",
        "columnnames": ["a", "b", "c"],
        "columntypes": ["integer", "character varying(30)", "timestamp without
time zone"],
        "columnvalues": [3, "Replication", "2018-03-27 12:05:29.914496"]
    },
    {
        "kind": "message",
        "transactional": true,
        "prefix": "wal2json",
        "content": "this message will be delivered"
    },
    {
        "kind": "delete",
        "schema": "public",
        "table": "table2_with_pk",
        "oldkeys": {
            "keynames": ["a", "c"],
            "keytypes": ["integer", "timestamp without time zone"],
            "keyvalues": [1, "2018-03-27 12:05:29.914496"]
        }
    },
    {
        "kind": "delete",
        "schema": "public",
        "table": "table2_with_pk",
        "oldkeys": {
            "keynames": ["a", "c"],
            "keytypes": ["integer", "timestamp without time zone"],
            "keyvalues": [2, "2018-03-27 12:05:29.914496"]
        }
    },
    {
        "kind": "insert",
        "schema": "public",
        "table": "table2_without_pk",
        "columnnames": ["a", "b", "c"],
        "columntypes": ["integer", "numeric(5,2)", "text"],
        "columnvalues": [1, 2.34, "Tapir"]
    }
]
```

```
}
stop
DROP TABLE
DROP TABLE
```

If `format-version` is set to 2, the script might look like this:

```
$ cat /tmp/example3.sql
CREATE TABLE table3_with_pk (a SERIAL, b VARCHAR(30), c TIMESTAMP NOT NULL,
PRIMARY KEY(a, c));
CREATE TABLE table3_without_pk (a SERIAL, b NUMERIC(5,2), c TEXT);

SELECT 'init' FROM pg_create_logical_replication_slot('test_slot', 'wal2json');

BEGIN;
INSERT INTO table3_with_pk (b, c) VALUES('Backup and Restore', now());
INSERT INTO table3_with_pk (b, c) VALUES('Tuning', now());
INSERT INTO table3_with_pk (b, c) VALUES('Replication', now());
SELECT pg_logical_emit_message(true, 'wal2json', 'this message will be
delivered');
SELECT pg_logical_emit_message(true, 'pgoutput', 'this message will be
filtered');
DELETE FROM table3_with_pk WHERE a < 3;
SELECT pg_logical_emit_message(false, 'wal2json', 'this non-transactional
message will be delivered even if you rollback the transaction');

INSERT INTO table3_without_pk (b, c) VALUES(2.34, 'Tapir');
-- it is not added to stream because there isn't a pk or a replica identity
UPDATE table3_without_pk SET c = 'Anta' WHERE c = 'Tapir';
COMMIT;

SELECT data FROM pg_logical_slot_get_changes('test_slot', NULL, NULL, 'format-
version', '2', 'add-msg-prefixes', 'wal2json');
SELECT 'stop' FROM pg_drop_replication_slot('test_slot');

DROP TABLE table3_with_pk;
DROP TABLE table3_without_pk;
```

The expected output might look like this:

```
$ psql -At -f /tmp/example3.sql postgres
CREATE TABLE
CREATE TABLE
init
BEGIN
INSERT 0 1
INSERT 0 1
INSERT 0 1
3/78CB8F30
3/78CB8F88

Appendix I. Additional Supplied Programs

This appendix, [Appendix F](#), and [Appendix G](#) contain information regarding additional modules available in the Postgres Pro Standard distribution. See [Appendix F](#) and [Appendix G](#) for more information about the server extensions and plug-ins.

This appendix covers the utility programs. Once installed, they are found in the `bin` directory of the Postgres Pro Standard installation and can be used like any other program.

I.1. Additional PostgreSQL/Postgres Pro Client Applications

This section covers PostgreSQL/Postgres Pro additional client applications included in the Postgres Pro Standard distribution. They can be run from anywhere, independent of where the database server resides. See also [Postgres Pro Client Applications](#) for information about client applications that are part of the core Postgres Pro Standard distribution.

oid2name

oid2name — resolve OIDs and file nodes in a Postgres Pro data directory

Synopsis

```
oid2name [option...]
```

Description

oid2name is a utility program that helps administrators to examine the file structure used by Postgres Pro. To make use of it, you need to be familiar with the database file structure, which is described in [Chapter 70](#).

Note

The name “oid2name” is historical, and is actually rather misleading, since most of the time when you use it, you will really be concerned with tables' filenode numbers (which are the file names visible in the database directories). Be sure you understand the difference between table OIDs and table filenodes!

oid2name connects to a target database and extracts OID, filenode, and/or table name information. You can also have it show database OIDs or tablespace OIDs.

Options

oid2name accepts the following command-line arguments:

```
-f filenode
```

```
--filenode=filenode
```

show info for table with filenode *filenode*.

```
-i
```

```
--indexes
```

include indexes and sequences in the listing.

```
-o oid
```

```
--oid=oid
```

show info for table with OID *oid*.

```
-q
```

```
--quiet
```

omit headers (useful for scripting).

```
-s
```

```
--tablespaces
```

show tablespace OIDs.

```
-S
```

```
--system-objects
```

include system objects (those in `information_schema`, `pg_toast` and `pg_catalog` schemas).

```
-t tablename_pattern
```

```
--table=tablename_pattern
```

show info for table(s) matching *tablename_pattern*.

-V
--version

Print the oid2name version and exit.

-x
--extended

display more information about each object shown: tablespace name, schema name, and OID.

-?
--help

Show help about oid2name command line arguments, and exit.

oid2name also accepts the following command-line arguments for connection parameters:

-d *database*
--dbname=*database*

database to connect to.

-h *host*
--host=*host*

database server's host.

-H *host*

database server's host. Use of this parameter is *deprecated* as of Postgres Pro 12.

-p *port*
--port=*port*

database server's port.

-U *username*
--username=*username*

user name to connect as.

To display specific tables, select which tables to show by using `-o`, `-f` and/or `-t`. `-o` takes an OID, `-f` takes a filenode, and `-t` takes a table name (actually, it's a `LIKE` pattern, so you can use things like `foo%`). You can use as many of these options as you like, and the listing will include all objects matched by any of the options. But note that these options can only show objects in the database given by `-d`.

If you don't give any of `-o`, `-f` or `-t`, but do give `-d`, it will list all tables in the database named by `-d`. In this mode, the `-s` and `-i` options control what gets listed.

If you don't give `-d` either, it will show a listing of database OIDs. Alternatively you can give `-s` to get a tablespace listing.

Environment

PGHOST
PGPORT
PGUSER

Default connection parameters.

This utility, like most other Postgres Pro utilities, also uses the environment variables supported by libpq (see [Section 33.15](#)).

The environment variable `PG_COLOR` specifies whether to use color in diagnostic messages. Possible values are `always`, `auto` and `never`.

Notes

oid2name requires a running database server with non-corrupt system catalogs. It is therefore of only limited use for recovering from catastrophic database corruption situations.

Examples

```
$ # what's in this database server, anyway?
$ oid2name
All databases:
  Oid  Database Name  Tablespace
-----
 17228      alvherre  pg_default
 17255      regression pg_default
 17227      template0  pg_default
    1      template1  pg_default

$ oid2name -s
All tablespaces:
  Oid  Tablespace Name
-----
 1663      pg_default
 1664      pg_global
155151      fastdisk
155152      bigdisk

$ # OK, let's look into database alvherre
$ cd $PGDATA/base/17228

$ # get top 10 db objects in the default tablespace, ordered by size
$ ls -lS * | head -10
-rw----- 1 alvherre alvherre 136536064 sep 14 09:51 155173

```

Description

pg_probackup is a utility to manage backup and recovery of Postgres Pro database clusters. It is designed to perform periodic backups of the Postgres Pro instance that enable you to restore the server in case of a failure. pg_probackup supports PostgreSQL 11 or higher.

- [Overview](#)
- [Quick Start](#)
- [Installation and Setup](#)
- [Command-Line Reference](#)
- [Usage](#)

Overview

As compared to other backup solutions, `pg_probackup` offers the following benefits that can help you implement different backup strategies and deal with large amounts of data:

- **Incremental backup:** with three different incremental modes, you can plan the backup strategy in accordance with your data flow. Incremental backups allow you to save disk space and speed up backup as compared to taking full backups. It is also faster to restore the cluster by applying incremental backups than by replaying WAL files.
- **Incremental restore:** speed up restore from a backup by reusing valid unchanged pages available in PGDATA.
- **Validation:** automatic data consistency checks and on-demand backup validation without actual data recovery.
- **Verification:** on-demand verification of Postgres Pro instance with the `checkdb` command.
- **Retention:** managing WAL archive and backups in accordance with retention policy. You can configure retention policy based on recovery time or the number of backups to keep, as well as specify time to live (TTL) for a particular backup. Expired backups can be merged or deleted.
- **Parallelization:** running `backup`, `restore`, `merge`, `delete`, `validate`, and `checkdb` processes on multiple parallel threads.
- **Compression:** storing backup data in a compressed state to save disk space.
- **Deduplication:** saving disk space by excluding non-data files (such as `_vm` or `_fsm`) from incremental backups if these files have not changed since they were copied into one of the previous backups in this incremental chain.
- **Remote operations:** backing up Postgres Pro instance located on a remote system or restoring a backup remotely.
- **Backups from a standby:** avoiding extra load on the primary by taking backups from a standby server.
- **External directories:** backing up files and directories located outside of the Postgres Pro data directory (PGDATA), such as scripts, configuration files, logs, or SQL dump files.
- **Backup catalog:** getting the list of backups and the corresponding meta information in plain text or JSON formats.
- **Archive catalog:** getting the list of all WAL timelines and the corresponding meta information in plain text or JSON formats.
- **Partial restore:** restoring only the specified databases.
- **Catchup:** cloning a Postgres Pro instance for a fallen-behind standby server to “catch up” with the primary.

To manage backup data, `pg_probackup` creates a *backup catalog*. This is a directory that stores all backup files with additional meta information, as well as WAL archives required for point-in-time recovery. You can store backups for different instances in separate subdirectories of a single backup catalog.

Using `pg_probackup`, you can take full or incremental [backups](#):

- **FULL backups** contain all the data files required to restore the database cluster.
- **Incremental backups** operate at the page level, only storing the data that has changed since the previous backup. It allows you to save disk space and speed up the backup process as compared to taking full backups. It is also faster to restore the cluster by applying incremental backups than by replaying WAL files. `pg_probackup` supports the following modes of incremental backups:
 - **DELTA backup.** In this mode, `pg_probackup` reads all data files in the data directory and copies only those pages that have changed since the previous backup. This mode can impose read-only I/O pressure equal to a full backup.
 - **PAGE backup.** In this mode, `pg_probackup` scans all WAL files in the archive from the moment the previous full or incremental backup was taken. Newly created backups contain only the pages that were mentioned in WAL records. This requires all the WAL files since the previous backup to be present in the WAL archive. If the size of these files is comparable to the total size of the database cluster files, speedup is smaller, but the backup still takes less space. You have to configure WAL archiving as explained in [Setting up continuous WAL archiving](#) to make PAGE backups.

- **PTRACK backup.** In this mode, Postgres Pro tracks page changes on the fly. Continuous archiving is not necessary for it to operate. Each time a relation page is updated, this page is marked in a special PTRACK bitmap. Tracking implies some minor overhead on the database server operation, but speeds up incremental backups significantly.

Warning

After promoting a standby server to primary and switching [timelines](#), take the first backup in **either FULL or DELTA mode**. Using other backup modes in this case may result in data corruption.

`pg_probackup` can take only physical online backups, and online backups require WAL for consistent recovery. So regardless of the chosen backup mode (FULL, PAGE or DELTA), any backup taken with `pg_probackup` must use one of the following *WAL delivery modes*:

- **ARCHIVE.** Such backups rely on [continuous archiving](#) to ensure consistent recovery. This is the default WAL delivery mode.
- **STREAM.** Such backups include all the files required to restore the cluster to a consistent state at the time the backup was taken. Regardless of [continuous archiving](#) having been set up or not, the WAL segments required for consistent recovery are streamed via replication protocol during backup and included into the backup files. That's why such backups are called *autonomous*, or *stand-alone*.

Limitations

`pg_probackup` currently has the following limitations:

- The remote mode is not supported on Windows systems.
- On Unix systems, for Postgres Pro, a backup can be made only by the same OS user that has started the Postgres Pro server. For example, if Postgres Pro server is started by user `postgres`, the `backup` command must also be run by user `postgres`. To satisfy this requirement when taking backups in the [remote mode](#) using SSH, you must set `--remote-user` option to `postgres`.
- The Postgres Pro server from which the backup was taken and the restored server must be compatible by the [block_size](#) and [wal_block_size](#) parameters and have the same major release number. Depending on cluster configuration, Postgres Pro itself may apply additional restrictions, such as CPU architecture or `libc/icu` versions.

Quick Start

To quickly get started with `pg_probackup`, complete the steps below. This will set up FULL and DELTA backups in the remote mode and demonstrate some basic `pg_probackup` operations. In the following, these terms are used:

- `backup` — Postgres Pro role used to connect to the Postgres Pro cluster.
- `backupdb` — database used to connect to the Postgres Pro cluster.
- `backup_host` — host with the backup catalog.
- `backup_user` — user on `backup_host` running all `pg_probackup` operations.
- `/mnt/backups` — directory on `backup_host` where the backup catalog is stored.
- `postgres_host` — host with the Postgres Pro cluster.
- `postgres` — user on `postgres_host` under which Postgres Pro cluster processes are running.
- `/var/lib/pgpro/std-16/data` — Postgres Pro data directory on `postgres_host`.

Steps to perform:

1. Install `pg_probackup` on both `backup_host` and `postgres_host`.
2. [Set up an SSH connection](#) from `backup_host` to `postgres_host`.
3. [Configure](#) your database cluster for [STREAM backups](#).
4. Initialize the backup catalog:

```
backup_user@backup_host:~$ pg_probackup init -B /mnt/backups
INFO: Backup catalog '/mnt/backups' successfully initialized
```

5. Add a backup instance called mydb to the backup catalog:

```
backup_user@backup_host:~$ pg_probackup add-instance \
-B /mnt/backups \
-D /var/lib/pgpro/std-16/data \
--instance=node \
--remote-host=postgres_host \
--remote-user=postgres
INFO: Instance 'node' successfully initialized
```

6. Make a FULL backup:

```
backup_user@backup_host:~$ pg_probackup backup \
-B /mnt/backups \
-b FULL \
--instance=node \
--stream \
--compress-algorithm=zstd \
--remote-host=postgres_host \
--remote-user=postgres \
-U backup \
-d backupdb
INFO: Backup start, pg_probackup version: 2.7.3, instance: node, backup ID: SBOL6J,
backup mode: FULL, wal mode: STREAM, remote: true, compress-algorithm: zstd,
compress-level: 1
WARNING: pgpro_edition() function is old-style and will be removed in future major
release, use pgpro_edition GUC variable instead.
INFO: This PostgreSQL instance was initialized with data block checksums. Data
block corruption will be detected
INFO: Database backup start
INFO: wait for pg_backup_start()
INFO: PGDATA size: 96MB
INFO: Current Start LSN: 0/8000028, TLI: 1
INFO: Start transferring data files
INFO: Data files are transferred, time elapsed: 2s
INFO: wait for pg_stop_backup()
INFO: pg_stop_backup() successfully executed
INFO: stop_stream_lsn 0/9000000 currentpos 0/9000000
INFO: backup->stop_lsn 0/8004E40
INFO: Getting the Recovery Time from WAL
INFO: Syncing backup files to disk
INFO: Backup files are synced, time elapsed: 1s
INFO: Validating backup SBOL6J
INFO: Backup SBOL6J data files are valid
INFO: Backup SBOL6J resident size: 53MB
INFO: Backup SBOL6J completed
```

7. List the backups of the instance:

```
backup_user@backup_host:~$ pg_probackup show \
-B /mnt/backups \
--instance=node
```

```
=====
Instance  Version  ID      Recovery Time      Mode  WAL Mode  TLI
Time Data   WAL  Zalg  Zratio  Start LSN  Stop LSN  Status
=====
```

```
node      17      SBOL6J  2024-04-09 18:18:21.970314+03  FULL  STREAM      1/0
4s  37MB  16MB  zstd    2.57  0/8000028  0/8004E40  OK
```

8. Make an incremental backup in the DELTA mode:

```
backup_user@backup_host:~$ pg_probackup backup \
-B /mnt/backups \
-b DELTA \
--instance=node \
--stream \
--compress-algorithm=zstd \
--remote-host=postgres_host \
--remote-user=postgres \
-U backup \
-d backupdb
INFO: Backup start, pg_probackup version: 2.7.3, instance: node, backup ID: SBOL6N,
backup mode: DELTA, wal mode: STREAM, remote: true, compress-algorithm: zstd,
compress-level: 1
WARNING: pgpro_edition() function is old-style and will be removed in future major
release, use pgpro_edition GUC variable instead.
INFO: This PostgreSQL instance was initialized with data block checksums. Data
block corruption will be detected
INFO: Database backup start
INFO: wait for pg_backup_start()
INFO: Parent backup: SBOL6J
INFO: PGDATA size: 96MB
INFO: Current Start LSN: 0/9000028, TLI: 1
INFO: Parent Start LSN: 0/8000028, TLI: 1
INFO: Start transferring data files
INFO: Data files are transferred, time elapsed: 1s
INFO: wait for pg_stop_backup()
INFO: pg_stop_backup() successfully executed
INFO: stop_stream_lsn 0/A000000 currentpos 0/A000000
INFO: backup->stop_lsn 0/9000190
INFO: Getting the Recovery Time from WAL
INFO: Syncing backup files to disk
INFO: Backup files are synced, time elapsed: 0
INFO: Validating backup SBOL6N
INFO: Backup SBOL6N data files are valid
INFO: Backup SBOL6N resident size: 17MB
INFO: Backup SBOL6N completed
```

9. Add or modify some parameters in the pg_probackup configuration file, so that you do not have to specify them each time on the command line:

```
backup_user@backup_host:~$ pg_probackup set-config \
-B /mnt/backups \
--instance=node \
--remote-host=postgres_host \
--remote-user=postgres \
-U backup \
-d backupdb
```

10. Check the configuration of the instance:

```
backup_user@backup_host:~$ pg_probackup show-config \
-B /mnt/backups \
--instance=node
# Backup instance information
pgdata = /var/lib/pgpro/std-16/data
```

```
system-identifier = 7355886958826772732
xlog-seg-size = 16777216
# Connection parameters
pgdatabase = backupdb
pghost = postgres_host
pguser = backup
# Archive parameters
archive-timeout = 5min
# Logging parameters
log-level-console = INFO
log-level-file = OFF
log-format-console = PLAIN
log-format-file = PLAIN
log-filename = pg_probackup.log
log-rotation-size = 0TB
log-rotation-age = 0d
# Retention parameters
retention-redundancy = 0
retention-window = 0
wal-depth = 0
# Compression parameters
compress-algorithm = none
compress-level = 1
# Remote access parameters
remote-proto = ssh
remote-host = postgres_host
remote-user = postgres
```

Note that the parameters not modified via `set-config` retain their default values.

11. Make another incremental backup in the DELTA mode, omitting the parameters stored in the configuration file earlier:

```
backup_user@backup_host:~$ pg_probackup backup \
    -B /mnt/backups \
    -b DELTA \
    --instance=node \
    --stream \
    --compress-algorithm=zstd
INFO: Backup start, pg_probackup version: 2.7.3, instance: node, backup ID: SBOL6P,
    backup mode: DELTA, wal mode: STREAM, remote: true, compress-algorithm: zstd,
    compress-level: 1
WARNING: pgpro_edition() function is old-style and will be removed in future major
    release, use pgpro_edition GUC variable instead.
INFO: This PostgreSQL instance was initialized with data block checksums. Data
    block corruption will be detected
INFO: Database backup start
INFO: wait for pg_backup_start()
INFO: Parent backup: SBOL6N
INFO: PGDATA size: 96MB
INFO: Current Start LSN: 0/A000028, TLI: 1
INFO: Parent Start LSN: 0/9000028, TLI: 1
INFO: Start transferring data files
INFO: Data files are transferred, time elapsed: 1s
INFO: wait for pg_stop_backup()
INFO: pg_stop_backup() successfully executed
INFO: stop_stream_lsn 0/B000000 currentpos 0/B000000
INFO: backup->stop_lsn 0/A000190
INFO: Getting the Recovery Time from WAL
```

```
INFO: Syncing backup files to disk
INFO: Backup files are synced, time elapsed: 0
INFO: Validating backup SBOL6P
INFO: Backup SBOL6P data files are valid
INFO: Backup SBOL6P resident size: 17MB
INFO: Backup SBOL6P completed
```

12. List the backups of the instance again:

```
backup_user@backup_host:~$ pg_probackup show \
-B /mnt/backups \
--instance=node
```

Instance	Version	ID	Recovery Time	Mode	WAL Mode	TLI	
Time	Data	WAL	Zalg	Zratio	Start LSN	Stop LSN	Status
node	17	SBOL6P	2024-04-09 18:18:26.630175+03	DELTA	STREAM	1/1	
1s	1147kB	16MB	zstd	1.00	0/A000028	0/A000190	OK
node	17	SBOL6N	2024-04-09 18:18:25.015713+03	DELTA	STREAM	1/1	
2s	1160kB	16MB	zstd	1.04	0/9000028	0/9000190	OK
node	17	SBOL6J	2024-04-09 18:18:21.970314+03	FULL	STREAM	1/0	
4s	37MB	16MB	zstd	2.57	0/8000028	0/8004E40	OK

13. Restore the data from the latest available backup to an arbitrary location:

```
backup_user@backup_host:~$ pg_probackup restore \
-B /mnt/backups \
-D /var/lib/pgpro/std-16/staging-data \
--instance=node
INFO: Validating parents for backup SBOL6P
INFO: Validating backup SBOL6J
INFO: Backup SBOL6J data files are valid
INFO: Validating backup SBOL6N
INFO: Backup SBOL6N data files are valid
INFO: Validating backup SBOL6P
INFO: Backup SBOL6P data files are valid
INFO: Backup SBOL6P WAL segments are valid
INFO: Backup SBOL6P is valid.
INFO: Restoring the database from the backup starting at 2024-04-09 18:18:25+03 on
localhost
INFO: Start restoring backup files. PGDATA size: 112MB
INFO: Backup files are restored. Transferred bytes: 112MB, time elapsed: 2s
INFO: Restore incremental ratio (less is better): 100% (112MB/112MB)
INFO: Syncing restored files to disk
INFO: Restored backup files are synced, time elapsed: 1s
INFO: Restore of backup SBOL6P completed.
```

Installation and Setup

Once you have `pg_probackup` installed, complete the following setup:

- Initialize the backup catalog.
- Add a new backup instance to the backup catalog.
- Configure the database cluster to enable `pg_probackup` backups.
- Optionally, configure SSH for running `pg_probackup` operations in the remote mode.

Initializing the Backup Catalog

`pg_probackup` stores all WAL and backup files in the corresponding subdirectories of the backup catalog.

To initialize the backup catalog, run the following command:

```
pg_probackup init -B backup_dir
```

where *backup_dir* is the path to the backup catalog. If the *backup_dir* already exists, it must be empty. Otherwise, `pg_probackup` returns an error.

The user launching `pg_probackup` must have full access to the *backup_dir* directory.

`pg_probackup` creates the *backup_dir* backup catalog, with the following subdirectories:

- *wal/* — directory for WAL files.
- *backups/* — directory for backup files.

Once the backup catalog is initialized, you can add a new backup instance.

Adding a New Backup Instance

`pg_probackup` can store backups for multiple database clusters in a single backup catalog. To set up the required subdirectories, you must add a backup instance to the backup catalog for each database cluster you are going to back up.

To add a new backup instance, run the following command:

```
pg_probackup add-instance -B backup_dir -D data_dir --instance=instance_name  
[remote_options]
```

Where:

- *data_dir* is the data directory of the cluster you are going to back up. To set up and use `pg_probackup`, write access to this directory is required.
- *instance_name* is the name of the subdirectories that will store WAL and backup files for this cluster.
- [remote_options](#) are optional parameters that need to be specified only if *data_dir* is located on a remote system.

`pg_probackup` creates the *instance_name* subdirectories under the *backups/* and *wal/* directories of the backup catalog. The *backups/instance_name* directory contains the `pg_probackup.conf` configuration file that controls `pg_probackup` settings for this backup instance. If you run this command with the [remote_options](#), the specified parameters will be added to `pg_probackup.conf`.

For details on how to fine-tune `pg_probackup` configuration, see [the section called “Configuring pg_probackup”](#).

The user launching `pg_probackup` must have full access to *backup_dir* directory and at least read-only access to *data_dir* directory. If you specify the path to the backup catalog in the `BACKUP_PATH` environment variable, you can omit the corresponding option when running `pg_probackup` commands.

Note

For Postgres Pro 11 or higher, it is recommended to use the [group access](#) feature, so that backups can be done by any OS user in the same group as the cluster owner. In this case, the user should have read permissions for the cluster directory.

Configuring the Database Cluster

Although `pg_probackup` can be used by a superuser, it is recommended to create a separate role with the minimum permissions required for the chosen backup strategy. In these configuration instructions, the `backup` role is used as an example.

For security reasons, it is recommended to run the configuration SQL queries below in a separate database.

```
postgres=# CREATE DATABASE backupdb;
postgres=# \c backupdb
```

To perform a [backup](#), the following permissions for role `backup` are required only in the database **used for connection** to the Postgres Pro server.

For Postgres Pro versions 11 — 14:

```
BEGIN;
CREATE ROLE backup WITH LOGIN;
GRANT USAGE ON SCHEMA pg_catalog TO backup;
GRANT EXECUTE ON FUNCTION pg_catalog.current_setting(text) TO backup;
GRANT EXECUTE ON FUNCTION pg_catalog.set_config(text, text, boolean) TO backup;
GRANT EXECUTE ON FUNCTION pg_catalog.pg_is_in_recovery() TO backup;
GRANT EXECUTE ON FUNCTION pg_catalog.pg_start_backup(text, boolean, boolean) TO backup;
GRANT EXECUTE ON FUNCTION pg_catalog.pg_stop_backup(boolean, boolean) TO backup;
GRANT EXECUTE ON FUNCTION pg_catalog.pg_create_restore_point(text) TO backup;
GRANT EXECUTE ON FUNCTION pg_catalog.pg_switch_wal() TO backup;
GRANT EXECUTE ON FUNCTION pg_catalog.pg_last_wal_replay_lsn() TO backup;
GRANT EXECUTE ON FUNCTION pg_catalog.txid_current() TO backup;
GRANT EXECUTE ON FUNCTION pg_catalog.txid_current_snapshot() TO backup;
GRANT EXECUTE ON FUNCTION pg_catalog.txid_snapshot_xmax(txid_snapshot) TO backup;
GRANT EXECUTE ON FUNCTION pg_catalog.pg_control_checkpoint() TO backup;
COMMIT;
```

For Postgres Pro 15 or higher:

```
BEGIN;
CREATE ROLE backup WITH LOGIN;
GRANT USAGE ON SCHEMA pg_catalog TO backup;
GRANT EXECUTE ON FUNCTION pg_catalog.current_setting(text) TO backup;
GRANT EXECUTE ON FUNCTION pg_catalog.set_config(text, text, boolean) TO backup;
GRANT EXECUTE ON FUNCTION pg_catalog.pg_is_in_recovery() TO backup;
GRANT EXECUTE ON FUNCTION pg_catalog.pg_backup_start(text, boolean) TO backup;
GRANT EXECUTE ON FUNCTION pg_catalog.pg_backup_stop(boolean) TO backup;
GRANT EXECUTE ON FUNCTION pg_catalog.pg_create_restore_point(text) TO backup;
GRANT EXECUTE ON FUNCTION pg_catalog.pg_switch_wal() TO backup;
GRANT EXECUTE ON FUNCTION pg_catalog.pg_last_wal_replay_lsn() TO backup;
GRANT EXECUTE ON FUNCTION pg_catalog.txid_current() TO backup;
GRANT EXECUTE ON FUNCTION pg_catalog.txid_current_snapshot() TO backup;
GRANT EXECUTE ON FUNCTION pg_catalog.txid_snapshot_xmax(txid_snapshot) TO backup;
GRANT EXECUTE ON FUNCTION pg_catalog.pg_control_checkpoint() TO backup;
COMMIT;
```

In the [pg_hba.conf](#) file, allow connection to the database cluster on behalf of the `backup` role.

Since `pg_probackup` needs to read cluster files directly, `pg_probackup` must be started by (or connected to, if used in the remote mode) the OS user that has read access to all files and directories inside the data directory (`PGDATA`) you are going to back up.

Depending on whether you plan to take [standalone](#) or [archive](#) backups, Postgres Pro cluster configuration will differ, as specified in the sections below. To back up the database cluster from a standby server, run `pg_probackup` in the remote mode, or create PTRACK backups, additional setup is required.

For details, see the sections [Setting up STREAM Backups](#), [Setting up continuous WAL archiving](#), [Setting up Backup from Standby](#), [Configuring the Remote Mode](#), [Setting up Partial Restore](#), and [Setting up PTRACK Backups](#).

Setting up STREAM Backups

To set up the cluster for [STREAM](#) backups, complete the following steps:

- If the `backup` role does not exist, create it with the `REPLICATION` privilege when [Configuring the Database Cluster](#):

```
CREATE ROLE backup WITH LOGIN REPLICATION;
```

- If the `backup` role already exists, grant it with the `REPLICATION` privilege:

```
ALTER ROLE backup WITH REPLICATION;
```

- In the `pg_hba.conf` file, allow replication on behalf of the `backup` role.
- Make sure the parameter `max_wal_senders` is set high enough to leave at least one session available for the backup process.
- Set the parameter `wal_level` to be higher than `minimal`.

If you are planning to take PAGE backups in the STREAM mode or perform PITR with STREAM backups, you still have to configure WAL archiving, as explained in the section [Setting up continuous WAL archiving](#).

Once these steps are complete, you can start taking FULL, PAGE, DELTA, and PTRACK backups in the [STREAM WAL](#) mode.

Note

If you are planning to rely on `.pgpass` for authentication when running backup in STREAM mode, then `.pgpass` must contain credentials for `replication` database, used to establish connection via replication protocol. Example: `pghost:5432:replication:backup_user:my_strong_password`

Setting up Continuous WAL Archiving

Making backups in the PAGE backup mode, performing [PITR](#) and making backups with the [ARCHIVE WAL](#) delivery mode require [continuous WAL archiving](#) to be enabled. To set up continuous archiving in the cluster, complete the following steps:

- Make sure the `wal_level` parameter is higher than `minimal`.
- If you are configuring archiving on the primary, `archive_mode` must be set to `on` or `always`. To perform archiving on a standby, set this parameter to `always`.
- Set the `archive_command` parameter, as follows:

```
archive_command = '"install_dir/pg_probackup" archive-push -B "backup_dir" --  
instance=instance_name --wal-file-name=%f [remote_options]'
```

where `install_dir` is the installation directory of the `pg_probackup` version you are going to use, `backup_dir` and `instance_name` refer to the already initialized backup catalog instance for this database cluster, and `remote_options` only need to be specified to archive WAL on a remote host. For details about all possible `archive-push` parameters, see the section [archive-push](#).

Once these steps are complete, you can start making backups in the [ARCHIVE WAL](#) mode, backups in the PAGE backup mode, as well as perform [PITR](#).

You can view the current state of the WAL archive using the `show` command. For details, see [the section called “Viewing WAL Archive Information”](#).

If you are planning to make PAGE backups and/or backups with [ARCHIVE WAL](#) mode from a standby server that generates a small amount of WAL traffic, without long waiting for WAL segment to fill up, consider setting the `archive_timeout` Postgres Pro parameter **on the primary**. The value of this parameter should be slightly lower than the `--archive-timeout` setting (5 minutes by default), so that there is enough time for the rotated segment to be streamed to a standby and sent to WAL archive before the backup is aborted because of `--archive-timeout`.

Note

Instead of using the [archive-push](#) command provided by `pg_probackup`, you can use any other tool to set up continuous archiving as long as it delivers WAL segments into `backup_dir/wal/instance_name` directory. If compression is used, it should be `gzip`, and `.gz` suffix in filename is mandatory.

Note

Instead of configuring continuous archiving by setting the `archive_mode` and `archive_command` parameters, you can opt for using the [pg_receivewal](#) utility. In this case, `pg_receivewal -D directory` option should point to `backup_dir/wal/instance_name` directory. `pg_probackup` supports WAL compression that can be done by `pg_receivewal`. “Zero Data Loss” archive strategy can be achieved only by using `pg_receivewal`.

Setting up Backups from a Standby

`pg_probackup` can take backups from a standby server. This requires the following additional setup:

- On the standby server, set the [hot_standby](#) parameter to `on`.
- On the primary server, set the [full_page_writes](#) parameter to `on`.
- To perform standalone backups on a standby, complete all the steps in section [Setting up STREAM Backups](#).
- To perform archive backups on a standby, complete all steps in section [Setting up continuous WAL archiving](#).

Once these steps are complete, you can start taking FULL, PAGE, DELTA, or PTRACK backups with appropriate WAL delivery mode: ARCHIVE or STREAM, from the standby server.

Backups from a standby server have the following limitations:

- If a standby is promoted to a primary during the backup process, the backup fails.
- All WAL records required for the backup must contain sufficient full-page writes. This requires you to enable `full_page_writes` on the primary, and not to use tools like `pg_compresslog` as [archive_command](#) to remove full-page writes from WAL files.

Setting up Cluster Verification

Logical verification of a database cluster requires the following additional setup. Role `backup` is used as an example:

- Install the [amcheck](#) or [amcheck_next](#) extension **in every database** of the cluster:

```
CREATE EXTENSION amcheck;
```

- Grant the following permissions to the `backup` role **in every database** of the cluster:

```
GRANT SELECT ON TABLE pg_catalog.pg_am TO backup;
GRANT SELECT ON TABLE pg_catalog.pg_class TO backup;
GRANT SELECT ON TABLE pg_catalog.pg_database TO backup;
GRANT SELECT ON TABLE pg_catalog.pg_namespace TO backup;
GRANT SELECT ON TABLE pg_catalog.pg_extension TO backup;
GRANT EXECUTE ON FUNCTION bt_index_check(regclass) TO backup;
GRANT EXECUTE ON FUNCTION bt_index_check(regclass, bool) TO backup;
GRANT EXECUTE ON FUNCTION bt_index_check(regclass, bool, bool) TO backup;
```

Setting up Partial Restore

If you are planning to use partial restore, complete the following additional step:

- Grant the read-only access to `pg_catalog.pg_database` to the `backup` role only in the database **used for connection** to Postgres Pro server:

```
GRANT SELECT ON TABLE pg_catalog.pg_database TO backup;
```

Configuring the Remote Mode

`pg_probackup` supports the remote mode that allows you to perform backup, restore and WAL archiving operations remotely. In this mode, the backup catalog is stored on a local system, while Postgres Pro instance to backup and/or to restore is located on a remote system. Currently the only supported remote protocol is SSH.

Set up SSH

If you are going to use `pg_probackup` in remote mode via SSH, complete the following steps:

1. Install `pg_probackup` on both systems: `backup_host` and `postgres_host`.
2. For communication between the hosts set up a passwordless SSH connection between the `backup_user` user on `backup_host` and the `postgres` user on `postgres_host`:

```
backup_user@backup_host:~$ ssh-copy-id postgres@postgres_host
```

Where:

- `backup_host` is the system with *backup catalog*.
 - `postgres_host` is the system with the Postgres Pro cluster.
 - `backup_user` is the OS user on `backup_host` used to run `pg_probackup`.
 - `postgres` is the user on `postgres_host` under which Postgres Pro cluster processes are running. For Postgres Pro 11 or higher a more secure approach can be used thanks to [group access](#) feature.
3. If you are going to rely on [continuous WAL archiving](#), set up a passwordless SSH connection between the `postgres` user on `postgres_host` and the `backup` user on `backup_host`:

```
postgres@postgres_host:~$ ssh-copy-id backup_user@backup_host
```

4. Make sure `pg_probackup` on `postgres_host` can be located when a connection via SSH is made. For example, for Bash, you can modify `PATH` in `~/.bashrc` of the `postgres` user (above the line in `bashrc` that exits the script for non-interactive shells). Alternatively, for `pg_probackup` commands, specify the path to the directory containing the `pg_probackup` binary on `postgres_host` via the [--remote-path](#) option.

`pg_probackup` in the remote mode via SSH works as follows:

- Only the following commands can be launched in the remote mode: [add-instance](#), [backup](#), [restore](#), [delete](#), [catchup](#), [archive-push](#), and [archive-get](#).
- Operating in remote mode requires `pg_probackup` binary to be installed on both local and remote systems. The versions of local and remote binary must be the same.
- When started in the remote mode, the main `pg_probackup` process on the local system connects to the remote system via SSH and launches one or more agent processes on the remote system, which are called *remote agents*. The number of remote agents is equal to the `-j/--threads` setting.
- The main `pg_probackup` process uses remote agents to access remote files and transfer data between local and remote systems.
- Remote agents try to minimize the network traffic and the number of round-trips between hosts.
- The main process is usually started on `backup_host` and connects to `postgres_host`, but in case of `archive-push` and `archive-get` commands the main process is started on `postgres_host` and connects to `backup_host`.
- Once data transfer is complete, remote agents are terminated and SSH connections are closed.
- If an error condition is encountered by a remote agent, then all agents are terminated and error details are reported by the main `pg_probackup` process, which exits with an error.
- Compression is always done on `postgres_host`, while decompression is always done on `backup_host`.

Note

You can impose [additional restrictions](#) on SSH settings to protect the system in the event of account compromise.

Note

Setting the number of threads (`-j/--threads` option) to a value greater than 10 for `pg_probackup` working in the remote mode via SSH may result in the actual number of SSH connections exceeding the maximum allowed number of simultaneous SSH connections on the remote server and consequently lead to an “ERROR: Agent error: kex_exchange_identification: Connection closed by remote host” error. To correct the error, either reduce the number of `pg_probackup` threads or adjust the value of `MaxStartups` configuration parameter of the remote SSH server. If SSH is set up as a `xinetd` service on the remote server, adjust the value of the `xinetd per_source` configuration parameter rather than `MaxStartups`.

Setting up PTRACK Backups**Note**

PTRACK versions lower than 2.0 are deprecated and not supported. Postgres Pro Standard and Postgres Pro Enterprise versions starting with 11.9.1 contain PTRACK 2.0. Upgrade your server to avoid issues in backups that you will take in future and be sure to take fresh backups of your clusters with the upgraded PTRACK since the backups taken with PTRACK 1.x might be corrupt.

If you are going to use PTRACK backups, complete the following additional steps.

Note

The permissions required for the role that will perform PTRACK backups (the `backup` role in the examples below) are listed in [the section called “Configuring the Database Cluster”](#). The role must have permissions only in the database used for connection to the Postgres Pro server.

For Postgres Pro 11 or higher:

1. Create PTRACK extension in the database *used for connection* to the Postgres Pro server:

```
CREATE EXTENSION ptrack;
```
2. To enable tracking page updates, set `ptrack.map_size` parameter to a positive integer and restart the server.

For optimal performance, it is recommended to set `ptrack.map_size` to $N / 1024$, where N is the size of the Postgres Pro cluster, in MB. If you set this parameter to a lower value, PTRACK is more likely to map several blocks together, which leads to false-positive results when tracking changed blocks and increases the incremental backup size as unchanged blocks can also be copied into the incremental backup. Setting `ptrack.map_size` to a higher value does not affect PTRACK operation, but it is not recommended to set this parameter to a value higher than 1024.

Note

If you change the `ptrack.map_size` parameter value, the previously created PTRACK map file is cleared, and tracking newly changed blocks starts from scratch. Thus, you have to retake a full backup before taking incremental PTRACK backups after changing `ptrack.map_size`.

Usage

Creating a Backup

To create a backup, run the following command:

```
pg_probackup backup -B backup_dir --instance=instance_name -b backup_mode
```

Where *backup_mode* can take one of the following values: [FULL](#), [DELTA](#), [PAGE](#), and [PTRACK](#).

When restoring a cluster from an incremental backup, `pg_probackup` relies on the parent full backup and all the incremental backups between them, which is called “the backup chain”. Thus, to perform incremental backups, it is necessary to have the last parent full backup with the status `OK` or `DONE` in the directory. If the parent full backup has the `MERGING` or `MERGED` status, an incremental backup cannot be performed.

For example, if merge has already been launched with a single full backup, an attempt to perform an incremental backup will end with the following messages:

```
WARNING: Valid full backup on current timeline 1 is not found, trying to look up on
previous timelines
WARNING: Cannot find valid backup on previous timelines
ERROR: Create new full backup before an incremental one
```

ARCHIVE Mode

ARCHIVE is the default WAL delivery mode.

For example, to make a FULL backup in ARCHIVE mode, run:

```
pg_probackup backup -B backup_dir --instance=instance_name -b FULL
```

ARCHIVE backups rely on [continuous archiving](#) to get WAL segments required to restore the cluster to a consistent state at the time the backup was taken.

When a backup is taken, `pg_probackup` ensures that WAL files containing WAL records between `Start LSN` and `Stop LSN` actually exist in `backup_dir/wal/instance_name` directory. `pg_probackup` also ensures that WAL records between `Start LSN` and `Stop LSN` can be parsed. This precaution eliminates the risk of silent WAL corruption.

STREAM Mode

STREAM is the optional WAL delivery mode.

For example, to make a FULL backup in the STREAM mode, add the `--stream` flag to the command from the previous example:

```
pg_probackup backup -B backup_dir --instance=instance_name -b FULL --stream --temp-slot
```

The optional `--temp-slot` flag ensures that the required segments remain available if the WAL is rotated before the backup is complete.

Unlike backups in ARCHIVE mode, STREAM backups include all the WAL segments required to restore the cluster to a consistent state at the time the backup was taken.

During [backup](#) `pg_probackup` streams WAL files containing WAL records between `Start LSN` and `Stop LSN` to `backup_dir/backups/instance_name/backup_id/database/pg_wal` directory. To eliminate the risk of silent WAL corruption, `pg_probackup` also checks that WAL records between `Start LSN` and `Stop LSN` can be parsed.

Even if you are using [continuous archiving](#), STREAM backups can still be useful in the following cases:

- STREAM backups can be restored on the server that has no file access to WAL archive.

- STREAM backups enable you to restore the cluster state at the point in time for which WAL files in archive are no longer available.
- Backup in STREAM mode can be taken from a standby of a server that generates small amount of WAL traffic, without long waiting for WAL segment to fill up.

Page Validation

If [data_checksums](#) are enabled in the database cluster, `pg_probackup` uses this information to check correctness of data files during backup. While reading each page, `pg_probackup` checks whether the calculated checksum coincides with the checksum stored in the page header. This guarantees that the Postgres Pro instance and the backup itself have no corrupt pages. Note that `pg_probackup` reads database files directly from the filesystem, so under heavy write load during backup it can show false-positive checksum mismatches because of partial writes. If a page checksum mismatch occurs, the page is re-read and checksum comparison is repeated.

A page is considered corrupt if checksum comparison has failed more than 300 times. In this case, the backup is aborted.

Even if data checksums are not enabled, `pg_probackup` always performs sanity checks for page headers.

External Directories

To back up a directory located outside of the data directory, use the optional `--external-dirs` parameter that specifies the path to this directory. If you would like to add more than one external directory, you can provide several paths separated by colons on Linux systems or semicolons on Windows systems.

For example, to include `/etc/dir1` and `/etc/dir2` directories into the full backup of your `instance_name` instance that will be stored under the `backup_dir` directory on Linux, run:

```
pg_probackup backup -B backup_dir --instance=instance_name -b FULL --external-dirs=/etc/dir1:/etc/dir2
```

Similarly, to include `C:\dir1` and `C:\dir2` directories into the full backup on Windows, run:

```
pg_probackup backup -B backup_dir --instance=instance_name -b FULL --external-dirs=C:\dir1;C:\dir2
```

`pg_probackup` recursively copies the contents of each external directory into a separate subdirectory in the backup catalog. Since external directories included into different backups do not have to be the same, when you are restoring the cluster from an incremental backup, only those directories that belong to this particular backup will be restored. Any external directories stored in the previous backups will be ignored.

To include the same directories into each backup of your instance, you can specify them in the `pg_probackup.conf` configuration file using the [set-config](#) command with the `--external-dirs` option.

Performing Cluster Verification

To verify that Postgres Pro database cluster is not corrupt, run the following command:

```
pg_probackup checkdb [-B backup_dir [--instance=instance_name]] [-D data_dir] [connection_options]
```

This command performs physical verification of all data files located in the specified data directory by running page header sanity checks, as well as block-level checksum verification if checksums are enabled. If a corrupt page is detected, `checkdb` continues cluster verification until all pages in the cluster are validated.

By default, similar [page validation](#) is performed automatically while a backup is taken by `pg_probackup`. The `checkdb` command enables you to perform such page validation on demand, without taking any backup copies, even if the cluster is not backed up using `pg_probackup` at all.

To perform cluster verification, `pg_probackup` needs to connect to the cluster to be verified. In general, it is enough to specify the backup instance of this cluster for `pg_probackup` to determine the required

connection options. However, if `-B` and `--instance` options are omitted, you have to provide [connection options](#) and `data_dir` via environment variables or command-line options.

Physical verification cannot detect logical inconsistencies, missing or nullified blocks and entire files, or similar anomalies. Extensions [amcheck](#) and [amcheck_next](#) provide a partial solution to these problems.

If you would like, in addition to physical verification, to verify all indexes in all databases using these extensions, you can specify the `--amcheck` flag when running the [checkdb](#) command:

```
pg_probackup checkdb -D data_dir --amcheck [connection_options]
```

You can skip physical verification by specifying the `--skip-block-validation` flag. In this case, you can omit `backup_dir` and `data_dir` options, only [connection options](#) are mandatory:

```
pg_probackup checkdb --amcheck --skip-block-validation [connection_options]
```

Logical verification can be done more thoroughly with the `--heapallindexed` flag by checking that all heap tuples that should be indexed are actually indexed, but at the higher cost of CPU, memory, and I/O consumption.

Validating a Backup

`pg_probackup` calculates checksums for each file in a backup during the backup process. The process of checking checksums of backup data files is called *the backup validation*. By default, validation is run immediately after the backup is taken and right before the restore, to detect possible backup corruption.

If you would like to skip backup validation, you can specify the `--no-validate` flag when running [backup](#) and [restore](#) commands.

To ensure that all the required backup files are present and can be used to restore the database cluster, you can run the [validate](#) command with the exact [recovery target options](#) you are going to use for recovery.

For example, to check that you can restore the database cluster from a backup copy up to transaction ID 4242, run this command:

```
pg_probackup validate -B backup_dir --instance=instance_name --recovery-target-xid=4242
```

If validation completes successfully, `pg_probackup` displays the corresponding message. If validation fails, you will receive an error message with the exact time, transaction ID, and LSN up to which the recovery is possible.

If you specify `backup_id` via `-i/--backup-id` option, then only the backup copy with specified backup ID will be validated. If `backup_id` is specified with [recovery target options](#), the `validate` command will check whether it is possible to restore the specified backup to the specified recovery target.

For example, to check that you can restore the database cluster from a backup copy with the SBOL6P backup ID up to the specified timestamp, run this command:

```
pg_probackup validate -B backup_dir --instance=instance_name -i SBOL6P --recovery-target-time="2024-04-10 18:18:26+03"
```

If you specify the `backup_id` of an incremental backup, all its parents starting from FULL backup will be validated.

If you omit all the parameters, all backups are validated.

Restoring a Cluster

To restore the database cluster from a backup, run the [restore](#) command with at least the following options:

```
pg_probackup restore -B backup_dir --instance=instance_name -i backup_id
```

Where:

- *backup_dir* is the backup catalog that stores all backup files and meta information.
- *instance_name* is the backup instance for the cluster to be restored.
- *backup_id* specifies the backup to restore the cluster from. If you omit this option, `pg_probackup` uses the latest valid backup available for the specified instance. If you specify an incremental backup to restore, `pg_probackup` automatically restores the underlying full backup and then sequentially applies all the necessary increments.

Once the `restore` command is complete, start the database service.

If you restore [ARCHIVE](#) backups, perform [PITR](#), or specify the `--restore-as-replica` flag with the `restore` command to set up a standby server, `pg_probackup` creates a recovery configuration file once all data files are copied into the target directory. This file includes the minimal settings required for recovery, except for the password in the [primary_conninfo](#) parameter; you have to add the password manually or use the `--primary-conninfo` option, if required. For Postgres Pro 11, recovery settings are written into the `recovery.conf` file. Starting from Postgres Pro 12, `pg_probackup` writes these settings into the `probackup_recovery.conf` file and then includes it into `postgresql.auto.conf`.

If you are restoring a [STREAM](#) backup, the restore is complete at once, with the cluster returned to a self-consistent state at the point when the backup was taken. For [ARCHIVE](#) backups, Postgres Pro replays all available archived WAL segments, so the cluster is restored to the latest state possible within the current timeline. You can change this behavior by using the [recovery target options](#) with the `restore` command, as explained in [the section called “Performing Point-in-Time \(PITR\) Recovery”](#).

If the cluster to restore contains tablespaces, `pg_probackup` restores them to their original location by default. To restore tablespaces to a different location, use the `--tablespace-mapping/-T` option. Otherwise, restoring the cluster on the same host will fail if tablespaces are in use, because the backup would have to be written to the same directories.

When using the `--tablespace-mapping/-T` option, you must provide absolute paths to the old and new tablespace directories. If a path happens to contain an equals sign (=), escape it with a backslash. This option can be specified multiple times for multiple tablespaces. For example:

```
pg_probackup restore -B backup_dir --instance=instance_name -D data_dir -j 4 -
i backup_id -T tablespace1_dir=tablespace1_newdir -T tablespace2_dir=tablespace2_newdir
```

To restore the cluster on a remote host, follow the instructions in [the section called “Using pg_probackup in the Remote Mode”](#).

Note

By default, the [restore](#) command validates the specified backup before restoring the cluster. If you run regular backup validations and would like to save time when restoring the cluster, you can specify the `--no-validate` flag to skip validation and speed up the recovery.

Incremental Restore

The speed of restore from backup can be significantly improved by replacing only invalid and changed pages in already existing Postgres Pro data directory using [incremental restore options](#) with the `restore` command.

To restore the database cluster from a backup in incremental mode, run the `restore` command with the following options:

```
pg_probackup restore -B backup_dir --instance=instance_name -D data_dir -
I incremental_mode
```

Where *incremental_mode* can take one of the following values:

- **CHECKSUM** — read all data files in the data directory, validate header and checksum in every page and replace only invalid pages and those with checksum and LSN not matching with corresponding page in backup. This is the simplest, the most fool-proof incremental mode. Recommended to use by default.
- **LSN** — read the `pg_control` in the data directory to obtain redo LSN and redo TLI, which allows you to determine a point in history(shiftpoint), where data directory state shifted from target backup chain history. If shiftpoint is not within reach of backup chain history, then restore is aborted. If shiftpoint is within reach of backup chain history, then read all data files in the data directory, validate header and checksum in every page and replace only invalid pages and those with LSN greater than shiftpoint. This mode offers a greater speed up compared to CHECKSUM, but rely on two conditions to be met. First, `data_checksums` parameter must be enabled in data directory (to avoid corruption due to hint bits). This condition will be checked at the start of incremental restore and the operation will be aborted if checksums are disabled. Second, the `pg_control` file must be synched with state of data directory. This condition cannot be checked at the start of restore, so it is a user responsibility to ensure that `pg_control` contain valid information. Therefore it is not recommended to use LSN mode in any situation, where `pg_control` cannot be trusted or has been tampered with: after `pg_resetxlog` execution, after restore from backup without recovery been run, etc.
- **NONE** — regular restore without any incremental optimizations.

Regardless of chosen incremental mode, `pg_probackup` will check, that postmaster in given destination directory is not running and `system-identifier` is the same as in the backup.

Suppose you want to return an old primary as a replica after switchover using incremental restore in LSN mode:

Instance	Version	ID	Recovery Time		Mode		WAL Mode	TLI	Time
Data	WAL	Zalg	Zratio	Start LSN	Stop LSN	Status			
node	17		SBOL8S	2024-04-09 18:19:43.707720+03	DELTA	STREAM	16/15

Note

Incremental restore is possible only for backups with `program_version` equal or greater than 2.4.0.

Partial Restore

If you have enabled [partial restore](#) before taking backups, you can restore only some of the databases using [partial restore options](#) with the [restore](#) commands.

To restore the specified databases only, run the [restore](#) command with the following options:

```
pg_probackup restore -B backup_dir --instance=instance_name --db-include=database_name
```

The `--db-include` option can be specified multiple times. For example, to restore only databases `db1` and `db2`, run the following command:

```
pg_probackup restore -B backup_dir --instance=instance_name --db-include=db1 --db-include=db2
```

To exclude one or more databases from restore, use the `--db-exclude` option:

```
pg_probackup restore -B backup_dir --instance=instance_name --db-exclude=database_name
```

The `--db-exclude` option can be specified multiple times. For example, to exclude the databases `db1` and `db2` from restore, run the following command:

```
pg_probackup restore -B backup_dir --instance=instance_name --db-exclude=db1 --db-exclude=db2
```

Partial restore relies on lax behavior of Postgres Pro recovery process toward truncated files. For recovery to work properly, files of excluded databases are restored as files of zero size. After the Postgres Pro cluster is successfully started, you must drop the excluded databases using `DROP DATABASE` command.

To decouple a single cluster containing multiple databases into separate clusters with minimal downtime, you can do partial restore of the cluster as a standby using the `--restore-as-replica` option for specific databases.

Note

The `template0` and `template1` databases are always restored.

Note

Due to recovery specifics of Postgres Pro versions earlier than 12, it is advisable that you set the [hot_standby](#) parameter to `off` when running partial restore of a Postgres Pro cluster of version earlier than 12. Otherwise the recovery may fail.

Performing Point-in-Time (PITR) Recovery

If you have enabled [continuous WAL archiving](#) before taking backups, you can restore the cluster to its state at an arbitrary point in time (recovery target) using [recovery target options](#) with the [restore](#) command.

You can use both STREAM and ARCHIVE backups for point in time recovery as long as the WAL archive is available at least starting from the time the backup was taken. If `-i/--backup-id` option is omitted, `pg_probackup` automatically chooses the backup that is the closest to the specified recovery target and starts the restore process, otherwise `pg_probackup` will try to restore the specified backup to the specified recovery target.

- To restore the cluster state at the exact time, specify the `--recovery-target-time` option, in the timestamp format. For example:

```
pg_probackup restore -B backup_dir --instance=instance_name --recovery-target-time="2024-04-10 18:18:26+03"
```

- To restore the cluster state up to a specific transaction ID, use the `--recovery-target-xid` option:

```
pg_probackup restore -B backup_dir --instance=instance_name --recovery-target-xid=687
```

- To restore the cluster state up to the specific LSN, use `--recovery-target-lsn` option:

```
pg_probackup restore -B backup_dir --instance=instance_name --recovery-target-lsn=16/B374D848
```

- To restore the cluster state up to the specific named restore point, use `--recovery-target-name` option:

```
pg_probackup restore -B backup_dir --instance=instance_name --recovery-target-name="before_app_upgrade"
```

- To restore the backup to the latest state available in the WAL archive, use `--recovery-target` option with `latest` value:

```
pg_probackup restore -B backup_dir --instance=instance_name --recovery-target="latest"
```

- To restore the cluster to the earliest point of consistency, use `--recovery-target` option with the `immediate` value:

```
pg_probackup restore -B backup_dir --instance=instance_name --recovery-target='immediate'
```

Using `pg_probackup` in the Remote Mode

`pg_probackup` supports the remote mode that allows you to perform backup and restore operations remotely via SSH. In this mode, the backup catalog is stored on a local system, while Postgres Pro instance to be backed up is located on a remote system. You must have `pg_probackup` installed on both systems.

Note

`pg_probackup` relies on passwordless SSH connection for communication between the hosts.

Note

In addition to SSH connection, `pg_probackup` uses a regular connection to the database to manage the remote operation. See the section [Configuring the Database Cluster](#) for details of how to set up a database connection.

The typical workflow is as follows:

- On your backup host, configure `pg_probackup` as explained in the section [Installation and Setup](#). For the `add-instance` and `set-config` commands, make sure to specify [remote mode options](#) that point to the database host with the Postgres Pro instance.
- If you would like to take remote backups in [PAGE](#) mode, or rely on [ARCHIVE](#) WAL delivery mode, or use [PITR](#), configure continuous WAL archiving from the database host to the backup host as explained in the section [Setting up continuous WAL archiving](#). For the `archive-push` and `archive-get` commands, you must specify the [remote mode options](#) that point to the backup host with the backup catalog.
- Run `backup` or `restore` commands with [remote mode options on the backup host](#). `pg_probackup` connects to the remote system via SSH and creates a backup locally or restores the previously taken backup on the remote system, respectively.

For example, to create an archive full backup of a Postgres Pro cluster located on a remote system with host address `192.168.0.2` on behalf of the `postgres` user via SSH connection through port `2302`, run:

```
pg_probackup backup -B backup_dir --instance=instance_name -b FULL --remote-user=postgres --remote-host=192.168.0.2 --remote-port=2302
```

To restore the latest available backup on a remote system with host address `192.168.0.2` on behalf of the `postgres` user via SSH connection through port `2302`, run:

```
pg_probackup restore -B backup_dir --instance=instance_name --remote-user=postgres --remote-host=192.168.0.2 --remote-port=2302
```

Restoring an [ARCHIVE](#) backup or performing [PITR](#) in the remote mode require additional information: destination address, port and username for establishing an SSH connection **from** the host with database **to** the host with the backup catalog. This information will be used by the `restore_command` to copy WAL segments from the archive to the Postgres Pro `pg_wal` directory.

To solve this problem, you can use [Remote WAL Archive Options](#).

For example, to restore latest backup on remote system using remote mode through SSH connection to user `postgres` on host with address `192.168.0.2` via port `2302` and user `backup` on backup catalog host with address `192.168.0.3` via port `2303`, run:

```
pg_probackup restore -B backup_dir --instance=instance_name --remote-user=postgres --remote-host=192.168.0.2 --remote-port=2302 --archive-host=192.168.0.3 --archive-port=2303 --archive-user=backup
```

Provided arguments will be used to construct the `restore_command`:

```
restore_command = '"install_dir/pg_probackup" archive-get -B "backup_dir" --instance=instance_name --wal-file-path=%p --wal-file-name=%f --remote-host=192.168.0.3 --remote-port=2303 --remote-user=backup'
```

Alternatively, you can use the `--restore-command` option to provide the entire `restore_command`:

```
pg_probackup restore -B backup_dir --instance=instance_name --remote-user=postgres --remote-host=192.168.0.2 --remote-port=2302 --restore-command='"install_dir/pg_probackup" archive-get -B "backup_dir" --instance=instance_name --wal-file-path=%p --wal-file-name=%f --remote-host=192.168.0.3 --remote-port=2303 --remote-user=backup'
```

Note

The remote mode is currently unavailable for Windows systems.

Running `pg_probackup` on Parallel Threads

`backup`, `restore`, `merge`, `delete`, `catchup`, `checkdb`, and `validate` processes can be executed on several parallel threads. This can significantly speed up `pg_probackup` operation given enough resources (CPU cores, disk, and network bandwidth).

Parallel execution is controlled by the `-j/--threads` command-line option. For example, to create a backup using four parallel threads, run:

```
pg_probackup backup -B backup_dir --instance=instance_name -b FULL -j 4
```

Note

Parallel restore applies only to copying data from the backup catalog to the data directory of the cluster. When Postgres Pro server is started, WAL records need to be replayed, and this cannot be done in parallel.

Important

A technique is implemented that prevents repeatable copying of one file when `pg_probackup` runs on multiple threads. With this technique, however, when disks are slow or the system is overloaded, parallel copying might fail. To handle this situation, resolve issues with your system resources.

Configuring `pg_probackup`

Once the backup catalog is initialized and a new backup instance is added, you can use the `pg_probackup.conf` configuration file located in the `backup_dir/backups/instance_name` directory to fine-tune `pg_probackup` configuration.

For example, `backup` and `checkdb` commands use a regular Postgres Pro connection. To avoid specifying [connection options](#) each time on the command line, you can set them in the `pg_probackup.conf` configuration file using the [set-config](#) command.

Note

It is **not recommended** to edit `pg_probackup.conf` manually.

Initially, `pg_probackup.conf` contains the following settings:

- `PGDATA` — the path to the data directory of the cluster to back up.
- `system-identifier` — the unique identifier of the Postgres Pro instance.

Additionally, you can define [remote mode](#), [retention](#), [logging](#), and [compression](#) settings using the `set-config` command:

```
pg_probackup set-config -B backup_dir --instance=instance_name  
[--external-dirs=external_directory_path] [remote_options] [connection_options]  
[retention_options] [logging_options]
```

To view the current settings, run the following command:

```
pg_probackup show-config -B backup_dir --instance=instance_name
```

You can override the settings defined in `pg_probackup.conf` when running `pg_probackup` [commands](#) via the corresponding environment variables and/or command line options.

Specifying Connection Settings

If you define connection settings in the `pg_probackup.conf` configuration file, you can omit connection options in all the subsequent `pg_probackup` commands. However, if the corresponding environment variables are set, they get higher priority. The options provided on the command line overwrite both environment variables and configuration file settings.

If nothing is given, the default values are taken. By default `pg_probackup` tries to use local connection via Unix domain socket (`localhost` on Windows) and tries to get the database name and the user name from the `PGUSER` environment variable or the current OS user name.

Managing the Backup Catalog

With `pg_probackup`, you can manage backups from the command line:

- [View backup information](#)
- [View WAL Archive Information](#)
- [Validate backups](#)
- [Merge backups](#)
- [Delete backups](#)

Viewing Backup Information

To view the list of existing backups for every instance, run the command:

```
pg_probackup show -B backup_dir
```

`pg_probackup` displays the list of all the available backups. For example:

```
BACKUP INSTANCE 'node'
```

=====										
Instance	Version	ID	Recovery Time		Mode		WAL Mode	TLI	Time

144MB	16MB	zstd	2.47	0/22000028	0/220001C8	OK				

For each backup, the following information is provided:

- Instance — the instance name.
- Version — Postgres Pro major version.
- ID — the backup identifier.
- Recovery time — the earliest moment for which you can restore the state of the database cluster.
- Mode — the method used to take this backup. Possible values: FULL, PAGE, DELTA, PTRACK.
- WAL Mode — WAL delivery mode. Possible values: STREAM and ARCHIVE.
- TLI — timeline identifiers of the current backup and its parent.
- Time — the time it took to perform the backup.
- Data — the size of the data files in this backup. This value does not include the size of WAL files. For STREAM backups, the total size of the backup can be calculated as `Data + WAL`.
- WAL — the uncompressed size of WAL files that need to be applied during recovery for the backup to reach a consistent state.
- compress-alg — compression algorithm used during backup. Possible values: zlib, pglz, lz4, zstd, none.

- `Zratio` — compression ratio calculated as “uncompressed-bytes” / “data-bytes”.
- `Start LSN` — WAL log sequence number corresponding to the start of the backup process. REDO point for Postgres Pro recovery process to start from.
- `Stop LSN` — WAL log sequence number corresponding to the end of the backup process. Consistency point for Postgres Pro recovery process.
- `Status` — backup status. Possible values:
 - `OK` — the backup is complete and valid.
 - `DONE` — the backup is complete, but was not validated.
 - `RUNNING` — the backup is in progress.
 - `MERGING` — the backup is being merged.
 - `MERGED` — the backup data files were successfully merged, but its metadata is in the process of being updated. Only full backups can have this status.
 - `DELETING` — the backup files are being deleted.
 - `CORRUPT` — some of the backup files are corrupt.
 - `ERROR` — the backup was aborted because of an unexpected error.
 - `ORPHAN` — the backup is invalid because one of its parent backups is corrupt or missing.
 - `HIDDEN_FOR_TEST` — a test script marked the backup as nonexistent. (`pg_probackup` never sets this status by itself.)

You can restore the cluster from the backup only if the backup status is `OK` or `DONE`.

To get more detailed information about the backup, run the `show` command with the backup ID:

```
pg_probackup show -B backup_dir --instance=instance_name -i backup_id
```

The sample output is as follows:

```
#Configuration
backup-mode = FULL
stream = false
compress-alg = lz4
compress-level = 1
from-replica = false

#Compatibility
block-size = 8192
xlog-block-size = 8192
checksum-version = 1
program-version = 2.7.3
server-version = 17

#Result backup info
timelineid = 1
start-lsn = 0/41000028
stop-lsn = 0/420000C0
start-time = '2024-04-09 18:19:52+03'
end-time = '2024-04-09 18:19:58+03'
end-validation-time = '2024-04-09 18:19:59+03'
recovery-xid = 757
recovery-time = '2024-04-09 18:19:56.603355+03'
data-bytes = 395651278
wal-bytes = 16777216
uncompressed-bytes = 578552566
pgdata-bytes = 578552248
status = OK
primary_conninfo = 'user=backup channel_binding=prefer host=localhost
port=5432 sslmode=prefer sslcompression=0 sslcertmode=allow sslsni=1'
```

```
ssl_min_protocol_version=TLSv1.2 gssencmode=prefer krbsrvname=postgres gssdelegation=0
target_session_attrs=any load_balance_hosts=disable'
content-crc = 3862224379
```

Detailed output has additional attributes:

- `compress-alg` — compression algorithm used during backup. Possible values: `zlib`, `pglz`, `lz4`, `zstd`, `none`.
- `compress-level` — compression level used during backup.
- `from-replica` — was this backup taken on a standby? Possible values: 1, 0.
- `block-size` — the [block_size](#) setting of Postgres Pro cluster at the backup start.
- `checksum-version` — are [data_checksums](#) enabled in the backed up Postgres Pro cluster? Possible values: 1, 0.
- `program-version` — full version of `pg_probackup` binary used to create the backup.
- `start-time` — the backup start time.
- `end-time` — the backup end time.
- `end-validation-time` — the backup validation end time.
- `expire-time` — the point in time when a pinned backup can be removed in accordance with retention policy. This attribute is only available for pinned backups.
- `uncompressed-bytes` — the size of data files before adding page headers and applying compression. You can evaluate the effectiveness of compression by comparing `uncompressed-bytes` to `data-bytes` if compression is used.
- `pgdata-bytes` — the size of Postgres Pro cluster data files at the time of backup. You can evaluate the effectiveness of an incremental backup by comparing `pgdata-bytes` to `uncompressed-bytes`.
- `recovery-xid` — transaction ID at the backup end time.
- `parent-backup-id` — ID of the parent backup. Available only for incremental backups.
- `primary_conninfo` — `libpq` connection parameters used to connect to the Postgres Pro cluster to take this backup. The password is not included.
- `note` — text note attached to backup.
- `content-crc` — CRC32 checksum of `backup_content.control` file. It is used to detect corruption of backup meta-information.

You can also get the detailed information about the backup in the JSON format:

```
pg_probackup show -B backup_dir --instance=instance_name --format=json -i backup_id
```

The sample output is as follows:

```

        "content-crc": 3862224379
    }
}
]

```

Viewing WAL Archive Information

To view the information about WAL archive for every instance, run the command:

```
pg_probackup show -B backup_dir [--instance=instance_name] --archive
```

pg_probackup displays the list of all the available WAL files grouped by timelines. For example:

```
ARCHIVE INSTANCE 'node'
```

TLI	Parent TLI	Switchpoint	Min Segno	Max Segno	N
segments	Size	Zratio	N backups	Status	
1	0	0/0	0000000100000000000000001B	00000001000000000000000042	40
	640MB	1.00	5	OK	

For each timeline, the following information is provided:

- **TLI** — timeline identifier.
- **Parent TLI** — identifier of the timeline from which this timeline branched off.
- **Switchpoint** — LSN of the moment when the timeline branched off from its parent timeline.
- **Min Segno** — the first WAL segment belonging to the timeline.
- **Max Segno** — the last WAL segment belonging to the timeline.
- **N segments** — number of WAL segments belonging to the timeline.
- **Size** — the size that files take on disk.
- **Zalg** — compression algorithm used during backup. Possible values: `zlib`, `pglz`, `lz4`, `zstd`, `none`.
- **Zratio** — compression ratio calculated as $N \text{ segments} * \text{wal\_segment\_size} * \text{wal\_block\_size} / \text{Size}$.
- **N backups** — number of backups belonging to the timeline. To get the details about backups, use the JSON format.
- **Status** — status of the WAL archive for this timeline. Possible values:
 - **OK** — all WAL segments between **Min Segno** and **Max Segno** are present.
 - **DEGRADED** — some WAL segments between **Min Segno** and **Max Segno** are missing. To find out which files are lost, view this report in the JSON format. This status may appear if several WAL files (in the middle of the sequence) were deleted by the `delete` command with the `--delete-wal` option according to the retention policy. This status does not affect the restore correctness, but it can be impossible to perform PITR of the cluster to some recovery targets.

To get more detailed information about the WAL archive in the JSON format, run the command:

```
pg_probackup show -B backup_dir [--instance=instance_name] --archive --format=json
```

Most fields are consistent with the plain format, with some exceptions:

- The size is in bytes.
- The `closest-backup-id` attribute contains the ID of the most recent valid backup that belongs to one of the previous timelines. You can use this backup to perform point-in-time recovery to this timeline. If such a backup does not exist, this string is empty.
- The `lost-segments` array provides with information about intervals of missing segments in `DEGRADED` timelines. In `OK` timelines, the `lost-segments` array is empty.
- The `backups` array lists all backups belonging to the timeline. If the timeline has no backups, this array is empty.

Configuring Retention Policy

With `pg_probackup`, you can configure retention policy to remove redundant backups, clean up unneeded WAL files, as well as pin specific backups to ensure they are kept for the specified time, as explained in the sections below. All these actions can be combined together in any way.

Removing Redundant Backups

By default, all backup copies created with `pg_probackup` are stored in the specified backup catalog. To save disk space, you can configure retention policy to remove redundant backup copies.

To configure retention policy, set one or more of the following variables in the `pg_probackup.conf` file via [set-config](#):

```
--retention-redundancy=redundancy
```

Specifies **the number of full backup copies** to keep in the backup catalog.

```
--retention-window=window
```

Defines the earliest point in time for which `pg_probackup` can complete the recovery. This option is set in **the number of days** from the current moment. For example, if `retention-window=7`, `pg_probackup` must keep at least one backup copy that is older than seven days, with all the corresponding WAL files, and all the backups that follow.

If both `--retention-redundancy` and `--retention-window` options are set, both these conditions have to be taken into account when purging the backup catalog. For example, if you set `--retention-redundancy=2` and `--retention-window=7`, `pg_probackup` has to keep two full backup copies, as well as all the backups required to ensure recoverability for the last seven days:

```
pg_probackup set-config -B backup_dir --instance=instance_name --retention-redundancy=2
--retention-window=7
```

It is recommended to always keep at least two last parent full backups to avoid errors when creating incremental backups.

To clean up the backup catalog in accordance with retention policy, you have to run the `delete` command with `retention flags`, as shown below, or use the `backup` command with these flags to process the outdated backup copies right when the new backup is created.

For example, to remove all backup copies that no longer satisfy the defined retention policy, run the following command with the `--delete-expired` flag:

```
pg_probackup delete -B backup_dir --instance=instance_name --delete-expired
```

If you would like to also remove the WAL files that are no longer required for any of the backups, you should also specify the `--delete-wal` flag:

```
pg_probackup delete -B backup_dir --instance=instance_name --delete-expired --delete-wal
```

You can also set or override the current retention policy by specifying `--retention-redundancy` and `--retention-window` options directly when running `delete` or `backup` commands:

```
pg_probackup delete -B backup_dir --instance=instance_name --delete-expired --retention-window=7 --retention-redundancy=2
```

Since incremental backups require that their parent full backup and all the preceding incremental backups are available, if any of such backups expire, they still cannot be removed while at least one incremental backup in this chain satisfies the retention policy. To avoid keeping expired backups that are still required to restore an active incremental one, you can merge them with this backup using the `--merge-expired` flag when running `backup` or `delete` commands.

Suppose you have backed up the `node` instance in the `backup_dir` directory, with the `--retention-window` option set to 6 and `--retention-redundancy` option set to 2, and you have the following backups available on August 01, 2024:

```
BACKUP INSTANCE 'node'
```

16MB	zstd	1,07	0/5000028	0/60000C0	OK						
node	17		SGT4B1	2024-07-18	09:49:52+03	FULL	ARCHIVE	1/0	5s	11MB	
16MB	zstd	2,89	0/2000028	0/3003A28	OK						

If you run the `delete` command with the `--delete-expired` flag, the backups with IDs SGT4B1, SGUYZ2, and SGWTN3 will be removed as they are expired both according to the retention window and due to

redundancy (the required set of full backups has already been retained). SGUYZ2 and SGWTN3 will also be removed since the base full backup is expired.

Running the `delete` command with the `--merge-expired` flag will merge backups SH48B3 and SH62Z5 with SH9SB5. The merge will occur with SH9SB5 as it is the first non-expired delta backup, which can be merged with expired delta backups SH62Z5 and expired full backup SH48B3.

```
pg_probackup delete -B backup_dir --instance=node --delete-expired --merge-expired
pg_probackup show -B backup_dir
```

```
BACKUP INSTANCE 'node'
```

Instance		Version	ID	Recovery Time		Mode	WAL Mode	TLI	Time	Data

16MB	zstd	2,84	0/11000028	0/120000C0	OK					

The Time field for the merged backup displays the time required for the merge.

Pinning Backups

If you need to keep certain backups longer than the established retention policy allows, you can pin them for arbitrary time. For example:

```
pg_probackup set-backup -B backup_dir --instance=instance_name -i backup_id --ttl=30d
```

This command sets the expiration time of the specified backup to 30 days starting from the time indicated in its `recovery-time` attribute.

You can also explicitly set the expiration time for a backup using the `--expire-time` option. For example:

```
pg_probackup set-backup -B backup_dir --instance=instance_name -i backup_id --expire-time="2027-04-09 18:21:32+00"
```

Alternatively, you can use the `--ttl` and `--expire-time` options with the `backup` command to pin the newly created backup:

```
pg_probackup backup -B backup_dir --instance=instance_name -b FULL --ttl=30d
pg_probackup backup -B backup_dir --instance=instance_name -b FULL --expire-time="2027-04-09 18:21:32+00"
```

To check if the backup is pinned, run the `show` command:

```
pg_probackup show -B backup_dir --instance=instance_name -i backup_id
```

If the backup is pinned, it has the `expire-time` attribute that displays its expiration time:

```
...
recovery-time = '2024-04-09 18:21:32+00'
expire-time = '2027-04-09 18:21:32+00'
data-bytes = 22288792
...
```

You can unpin the backup by setting the `--ttl` option to zero:

```
pg_probackup set-backup -B backup_dir --instance=instance_name -i backup_id --ttl=0
```

Note

A pinned incremental backup implicitly pins all its parent backups. If you unpin such a backup later, its implicitly pinned parents will also be automatically unpinned.

Configuring WAL Archive Retention Policy

When [continuous WAL archiving](#) is enabled, archived WAL segments can take a lot of disk space. Even if you delete old backup copies from time to time, the `--delete-wal` flag can purge only those WAL segments that do not apply to any of the remaining backups in the backup catalog. However, if point-in-time recovery is critical only for the most recent backups, you can configure WAL archive retention policy to keep WAL archive of limited depth and win back some more disk space.

To configure WAL archive retention policy, you have to run the `set-config` command with the `--wal-depth` option that specifies the number of backups that can be used for PITR. This setting applies to all the timelines, so you should be able to perform PITR for the same number of backups on each timeline, if available. [Pinned backups](#) are not included into this count: if one of the latest backups is pinned, `pg_probackup` ensures that PITR is possible for one extra backup.

To remove WAL segments that do not satisfy the defined WAL archive retention policy, you simply have to run the `delete` or `backup` command with the `--delete-wal` flag. For archive backups, WAL segments between `Start LSN` and `Stop LSN` are always kept intact, so such backups remain valid regardless of the `--wal-depth` setting and can still be restored, if required.

You can also use the `--wal-depth` option with the `delete` and `backup` commands to override the previously defined WAL archive retention policy and purge old WAL segments on the fly.

Suppose you have backed up the `node` instance in the `backup_dir` directory and configured [continuous WAL archiving](#):

```
pg_probackup show -B backup_dir --instance=node
```

Instance	Version	ID	Recovery Time	Mode	WAL Mode	TLI	Time
Data	WAL	Zalg	Zratio	Start LSN	Stop LSN	Status	
node	17	SBOLDA	2024-04-09 18:22:23.147138+03	DELTA	STREAM	1/1	1s
1165kB	16MB	zstd	1.09	0/6F000028	0/6F000190	OK	
node	17	SBOLCY	2024-04-09 18:22:16.079841+03	FULL	STREAM	1/0	10s
278MB	16MB	zstd	2.46	0/6D000028	0/6D000190	OK	
node	17	SBOLCW	2024-04-09 18:22:10.154022+03	DELTA	STREAM	1/1	2s
1364kB	16MB	zstd	1.01	0/6B000028	0/6B000190	OK	
node	17	SBOLCS	2024-04-09 18:22:07.521646+03	DELTA	STREAM	1/1	4s
78MB	16MB	zstd	2.41	0/69000028	0/69000190	OK	
node	17	SBOLCC	2024-04-09 18:21:55.830115+03	FULL	STREAM	1/0	15s
278MB	96MB	zstd	2.46	0/600060C8	0/64FE6640	OK	
node	17	SBOLBW	2024-04-09 18:21:38.399702+03	FULL	STREAM	1/0	12s
278MB	96MB	zstd	2.46	0/54001830	0/589E5908	OK	

You can check the state of the WAL archive by running the `show` command with the `--archive` flag:

```
pg_probackup show -B backup_dir --instance=node --archive
```

```
ARCHIVE INSTANCE 'node'
```

TLI	Parent TLI	Switchpoint	Min Segno	Max Segno	N
segments	Size	Zratio	N backups	Status	

```
=====
1      0      0/0      0000000100000000000000052  000000010000000000000006F  30
      480MB  1.00      6      OK
```

WAL purge without `--wal-depth` cannot achieve much, only one segment is removed:

```
pg_probackup delete -B backup_dir --instance=node --delete-wal
```

```
ARCHIVE INSTANCE 'node'
```

```
=====
TLI   Parent TLI   Switchpoint   Min Segno           Max Segno           N
segments Size   Zratio   N backups   Status
=====
1      0      0/0      0000000100000000000000054  000000010000000000000006F  28
      448MB  1.00      6      OK
```

If you would like, for example, to keep only those WAL segments that can be applied to the latest valid backup, set the `--wal-depth` option to 1:

```
pg_probackup delete -B backup_dir --instance=node --delete-wal --wal-depth=1
```

```
ARCHIVE INSTANCE 'node'
```

```
=====
TLI   Parent TLI   Switchpoint   Min Segno           Max Segno           N
segments Size   Zratio   N backups   Status
=====
1      0      0/0      000000010000000000000006F  000000010000000000000006F  1
      16MB  1.00      6      OK
```

Alternatively, you can use the `--wal-depth` option with the `backup` command:

```
pg_probackup backup -B backup_dir --instance=node -b DELTA --wal-depth=1 --delete-wal
```

```
ARCHIVE INSTANCE 'node'
```

```
=====
TLI   Parent TLI   Switchpoint   Min Segno           Max Segno           N
segments Size   Zratio   N backups   Status
=====
1      0      0/0      0000000100000000000000071  0000000100000000000000071  1
      16MB  1.00      7      OK
```

Merging Backups

As you take more and more incremental backups, the total size of the backup catalog can substantially grow. To save disk space, you can merge incremental backups to their parent full backup by running the `merge` command, specifying the backup ID of the most recent incremental backup you would like to merge:

```
pg_probackup merge -B backup_dir --instance=instance_name -i backup_id
```

This command merges backups that belong to a common incremental backup chain. If you specify a full backup, it will be merged with its first incremental backup. If you specify an incremental backup, it will be merged to its parent full backup, together with all incremental backups between them. Once the merge is complete, the full backup takes in all the merged data, and the incremental backups are removed as redundant. Thus, the merge operation is virtually equivalent to retaking a full backup and removing all the outdated backups, but it allows you to save much time, especially for large data volumes, as well as I/O and network traffic if you are using `pg_probackup` in the `remote` mode.

Before the merge, `pg_probackup` validates all the affected backups to ensure that they are valid. You can check the current backup status by running the `show` command with the backup ID:

```
pg_probackup show -B backup_dir --instance=instance_name -i backup_id
```

If the merge is still in progress, the backup status is displayed as `MERGING`. For full backups, it can also be shown as `MERGED` while the metadata is being updated at the final stage of the merge. The merge is idempotent, so you can restart the merge if it was interrupted.

Warning

Avoid force-terminating the merge operation, as it may cause subsequent `merge` commands to fail and disrupt backup validation.

Deleting Backups

To delete a backup that is no longer required, run the following command:

```
pg_probackup delete -B backup_dir --instance=instance_name -i backup_id
```

This command will delete the backup with the specified `backup_id`, together with all the incremental backups that descend from `backup_id`, if any. This way you can delete some recent incremental backups, retaining the underlying full backup and some of the incremental backups that follow it.

To delete obsolete WAL files that are not necessary to restore any of the remaining backups, use the `--delete-wal` flag:

```
pg_probackup delete -B backup_dir --instance=instance_name --delete-wal
```

To delete backups that are expired according to the current retention policy, use the `--delete-expired` flag:

```
pg_probackup delete -B backup_dir --instance=instance_name --delete-expired
```

Expired backups cannot be removed while at least one incremental backup that satisfies the retention policy is based on them. If you would like to minimize the number of backups still required to keep incremental backups valid, specify the `--merge-expired` flag when running this command:

```
pg_probackup delete -B backup_dir --instance=instance_name --delete-expired --merge-expired
```

In this case, `pg_probackup` searches for the oldest incremental backup that satisfies the retention policy and merges this backup with the underlying full and incremental backups that have already expired, thus making it a full backup. Once the merge is complete, the remaining expired backups are deleted.

Before merging or deleting backups, you can run the `delete` command with the `--dry-run` flag, which displays the status of all the available backups according to the current retention policy, without performing any irreversible actions.

To delete all backups with specific status, use the `--status`:

```
pg_probackup delete -B backup_dir --instance=instance_name --status=ERROR
```

Deleting backups by status ignores established retention policies.

Cloning and Synchronizing Postgres Pro Instance

`pg_probackup` can create a copy of a Postgres Pro instance directly, without using the backup catalog. To do this, you can run the `catchup` command. It can be useful in the following cases:

- To add a new standby server.

Usually, `pg_basebackup` is used to create a copy of a Postgres Pro instance. If the data directory of the destination instance is empty, the `catchup` command works similarly, but it can be faster if run in parallel mode.

- To have a fallen-behind standby server “catch up” with the primary.

Under write-intensive load, replicas may fail to replay WAL fast enough to keep up with the primary and hence may lag behind. A usual solution to create a new replica and switch to it requires a lot of extra space and data transfer. The `catchup` command allows you to update an existing replica much faster by bringing differences from the primary.

`catchup` is different from other `pg_probackup` operations:

- The backup catalog is not required.
- STREAM WAL delivery mode is only supported.
- Copying external directories is not supported.
- DDL commands `CREATE TABLESPACE/DROP TABLESPACE` cannot be run simultaneously with `catchup`.
- `catchup` takes configuration files, such as `postgresql.conf`, `postgresql.auto.conf`, or `pg_hba.conf`, from the source server and overwrites them on the target server. The `--exclude-path` option allows you to keep the configuration files intact.

To prepare for cloning/synchronizing a Postgres Pro instance, set up the source server as follows:

- [Configure the database cluster](#) for the instance to copy.
- To copy from a remote server, [configure the remote mode](#).
- To use the PTRACK `catchup` mode, [set up PTRACK backups](#).

Before cloning/synchronizing a Postgres Pro instance, ensure that the source server is running and accepting connections. To clone/sync a Postgres Pro instance, on the server with the destination instance, you can run the `catchup` command as follows:

```
pg_probackup catchup -b catchup_mode --source-pgdata=path_to_pgdata_on_remote_server --  
destination-pgdata=path_to_local_dir --stream [connection_options] [remote_options]
```

Where *catchup_mode* can take one of the following values:

- `FULL` — creates a full copy of the Postgres Pro instance. The data directory of the destination instance must be empty for this mode.
- `DELTA` — reads all data files in the data directory and creates an incremental copy for pages that have changed since the destination instance was shut down.
- `PTRACK` — tracking page changes on the fly, only reads and copies pages that have changed since the point of divergence of the source and destination instances.

Warning

PTRACK `catchup` mode requires PTRACK not earlier than 2.0 and hence, Postgres Pro not earlier than 11.

By specifying the `--stream` option, you can set `STREAM` WAL delivery mode of copying, which will include all the necessary WAL files by streaming them from the server via replication protocol.

You can use [connection_options](#) to specify the connection to the source database cluster. If it is located on a different server, also specify [remote_options](#).

If the source database cluster contains tablespaces that must be located in a different directory, additionally specify the `--tablespace-mapping` option:

```
pg_probackup catchup -b catchup_mode --source-pgdata=path_to_pgdata_on_remote_server --  
destination-pgdata=path_to_local_dir --stream --tablespace-mapping=OLDDIR=NEWDIR
```

To run the `catchup` command on parallel threads, specify the number of threads with the `--threads` option:

```
pg_probackup catchup -b catchup_mode --source-pgdata=path_to_pgdata_on_remote_server --  
destination-pgdata=path_to_local_dir --stream --threads=num_threads
```

Before cloning/synchronising a Postgres Pro instance, you can run the `catchup` command with the `--dry-run` flag to estimate the size of data files to be transferred, but make no changes on disk:

```
pg_probackup catchup -b catchup_mode --source-pgdata=path_to_pgdata_on_remote_server --  
destination-pgdata=path_to_local_dir --stream --dry-run
```

For example, assume that a remote standby server with the Postgres Pro instance having `/replica-pgdata` data directory has fallen behind. To sync this instance with the one in `/master-pgdata` data directory, you can run the `catchup` command in the `PTRACK` mode on four parallel threads as follows:

```
pg_probackup catchup --source-pgdata=/master-pgdata --destination-pgdata=/replica-  
pgdata -p 5432 -d postgres -U remote-postgres-user --stream --backup-mode=PTRACK  
--remote-host=remote-hostname --remote-user=remote-unix-username -j 4 --exclude-  
path=postgresql.conf --exclude-path=postgresql.auto.conf --exclude-path=pg_hba.conf --  
exclude-path=pg_ident.conf
```

Note that in this example, the configuration files will not be overwritten during synchronization.

Another example shows how you can add a new remote standby server with the Postgres Pro data directory `/replica-pgdata` by running the `catchup` command in the `FULL` mode on four parallel threads:

```
pg_probackup catchup --source-pgdata=/master-pgdata --destination-pgdata=/replica-  
pgdata -p 5432 -d postgres -U remote-postgres-user --stream --backup-mode=FULL --  
remote-host=remote-hostname --remote-user=remote-unix-username -j 4
```

Command-Line Reference

Commands

This section describes `pg_probackup` commands. Optional parameters are enclosed in square brackets. For detailed parameter descriptions, see the section [Options](#).

version

```
pg_probackup version [--format=json]
```

Prints `pg_probackup` version and edition, as well as Postgres Pro version and edition.

If `--format=json` is specified, the output is printed in the JSON format. This may be needed for native integration with JSON-based applications, such as PPEM. Example of a JSON output:

```
pg_probackup version --format=json  
{  
  "pg_probackup":  
  {  
    "version": "2.8.2",  
    "edition": "community"  
  },  
  "database":  
  {  
    "type": "Postgres Pro Standard",  
    "version": "16.3.1"  
  },  
  "compressions": [zlib, pglz, lz4, zstd]  
}
```

help

```
pg_probackup help [command]
```

Displays the synopsis of `pg_probackup` commands. If one of the `pg_probackup` commands is specified, shows detailed information about the options that can be used with this command.

init

```
pg_probackup init -B backup_dir [--skip-if-exists] [--help]
[logging_options]
```

Initializes the backup catalog in *backup_dir* that will store backup copies, WAL archive, and meta information for the backed up database clusters. If the specified *backup_dir* already exists, it must be empty. Otherwise, `pg_probackup` displays a corresponding error message. You can ignore this error by specifying the `--skip-if-exists` option. Although the backup will not be initialized, the application will return 0 code.

For details, see the section [Initializing the Backup Catalog](#).

add-instance

```
pg_probackup add-instance -B backup_dir -D data_dir --instance=instance_name
[--skip-if-exists] [--help] [--wal-tree] [logging_options]
```

Initializes a new backup instance inside the backup catalog *backup_dir* and generates the `pg_probackup.conf` configuration file that controls `pg_probackup` settings for the cluster with the specified *data_dir* data directory.

`--skip-if-exists`

Allows skipping initialization without raising an error if an instance already exists.

`--wal-tree`

Sets WAL files to be stored in subdirectories, optimizing disk space. This prevents file system overload, especially NFS (Network File System), which can struggle with excessive files in a single directory.

For more details on the `add-instance` command, see the section [Adding a New Backup Instance](#).

del-instance

```
pg_probackup del-instance -B backup_dir --instance=instance_name [--help]
[logging_options]
```

Deletes all backups and WAL files associated with the specified instance.

set-config

```
pg_probackup set-config -B backup_dir --instance=instance_name
[--help] [--pgdata=pgdata-path]
[--retention-redundancy=redundancy] [--retention-window=window] [--wal-depth=wal_depth]
[--compress-algorithm=compression_algorithm] [--compress-level=compression_level]
[-d dbname] [-h host] [-p port] [-U username]
[--archive-timeout=timeout] [--external-dirs=external_directory_path]
[--restore-command=cmdline]
[remote_options] [remote_wal_archive_options] [logging_options]
```

Adds the specified connection, compression, retention, logging, and external directory settings into the `pg_probackup.conf` configuration file, or modifies the previously defined values.

For all available settings, see the [Options](#) section.

It is **not recommended** to edit `pg_probackup.conf` manually.

set-backup

```
pg_probackup set-backup -B backup_dir --instance=instance_name -i backup_id
{--ttl=ttl | --expire-time=time}
[--note=backup_note] [--help] [logging_options]
```

Sets the provided backup-specific settings into the `backup.control` configuration file, or modifies the previously defined values.

`--note=backup_note`

Sets the text note for backup copy. If `backup_note` contains newline characters, then only the substring before the first newline character will be saved. The maximum size of a text note is 1 KB. The `'none'` value removes the current note.

For all available pinning settings, see the section [Pinning Options](#).

show-config

```
pg_probackup show-config -B backup_dir --instance instance_name [--format=plain|json]
[--no-scale-units] [logging_options]
```

Displays all the current `pg_probackup` configuration settings, including those that are specified in the `pg_probackup.conf` configuration file located in the `backup_dir/backups/instance_name` directory and those that were provided on a command line. You can specify the `--format=json` option to get the result in the JSON format. By default, configuration settings are shown as plain text.

You can also specify the `--no-scale-units` option to display time and memory configuration settings in their base (unscaled) units. Otherwise, the values are scaled to larger units for optimal display. For example, if `archive-timeout` is 300, then 5min is displayed, but if `archive-timeout` is 301, then 301s is displayed. Also, if the `--no-scale-units` option is specified, configuration settings are displayed without units and for the JSON format, numeric and boolean values are not enclosed in quotes. This facilitates parsing the output.

To edit `pg_probackup.conf`, use the [set-config](#) command.

show

```
pg_probackup show -B backup_dir
[--help] [--instance=instance_name [-i backup_id | --archive]] [--format=plain|json]
[--no-color] [--show-symlinks]
[logging_options]
```

Shows the contents of the backup catalog. If `instance_name` and `backup_id` are specified, shows detailed information about this backup. If the `--archive` option is specified, shows the contents of WAL archive of the backup catalog.

By default, the contents of the backup catalog is shown as plain text. You can specify the `--format=json` option to get the result in the JSON format. If `--no-color` flag is used, then the output is not colored.

If the `--show-symlinks` option is specified, the command also shows the links between [merged](#) backups and the original full backups that incremental backups were merged to.

For details on usage, see the sections [Managing the Backup Catalog](#) and [Viewing WAL Archive Information](#).

backup

```
pg_probackup backup -B backup_dir -b backup_mode --instance=instance_name
[--help] [-j num_threads] [--progress]
[--backup-threads num_threads] [--validate-threads num_threads]
[-C] [--stream [-S slot_name] [--temp-slot [=true|false|on|off]]] [--backup-pg-log]
[--no-validate] [--skip-block-validation]
[-w --no-password] [-W --password] [--allow-group-access]
[--write-rate-limit=bitrate]
[--archive-timeout=timeout] [--external-dirs=external_directory_path]
[--no-sync] [--note=backup_note]
[connection_options] [compression_options] [remote_options]
[retention_options] [pinning_options] [logging_options]
```

Creates a backup copy of the Postgres Pro instance.

`-b mode`

`--backup-mode=mode`

Specifies the backup mode to use. Possible values are: [FULL](#), [DELTA](#), [PAGE](#), and [PTRACK](#).

`--backup-threads num_threads`

Specifies the number of threads for copying files. Overrides the `j/--threads` option for file copying.

`--validate-threads num_threads`

Specifies the number of threads for the backup validation. Overrides the `j/--threads` option for the backup validation.

`-C`

`--smooth-checkpoint`

Spreads out the checkpoint over a period of time. By default, `pg_probackup` tries to complete the checkpoint as soon as possible.

`--stream`

Makes a [STREAM](#) backup, which includes all the necessary WAL files by streaming them from the database server via replication protocol.

`--temp-slot [=true|false|on|off]`

Creates a *temporary* physical replication slot for streaming WAL from the backed up Postgres Pro instance. `--temp-slot` is enabled by default. It ensures that all the required WAL segments remain available if WAL is rotated while the backup is in progress. This flag can only be used together with the `--stream` flag. The default slot name is `pg_probackup_slot`. To change it, use the `--slot/-S` option and explicitly specify `--temp-slot` or `--temp-slot=true|on`.

`-S slot_name`

`--slot=slot_name`

Specifies the replication slot to connect to for WAL streaming. This option can only be used together with the `--stream` flag.

`--backup-pg-log`

Includes the log directory into the backup. This directory usually contains log messages. By default, log directory is excluded.

`-E external_directory_path`

`--external-dirs=external_directory_path`

Includes the specified directory into the backup by recursively copying its contents into a separate subdirectory in the backup catalog. This option is useful to back up scripts, SQL dump files, and configuration files located outside of the data directory. If you would like to back up several external directories, separate their paths by a colon on Unix and a semicolon on Windows.

`--allow-group-access`

Provides read access to backups stored on the backup host to any OS user in the same group as the OS user on the backup host who runs `pg_probackup` operations.

`--write-rate-limit=bitrate`

Sets the rate of writing data to disk, in MBps or GBps. The default unit is MBps. For example: `--write-rate-limit=1GBps` or `--write-rate-limit=100` (MBps). The default value is 0 — no limitation.

If this option is specified, the following information is displayed at the end of the backup:

- `written` — the amount of data written, in MB.
- `total time` — the time that elapsed between the first and last writes, in seconds. Note that this is not the total backup time.
- `sleep time` — the amount of forced delay time, in seconds.
- `average rate` — the actual average write rate, in MBps.

For example:

```
INFO: Rate limit: written 14975.445 MB, total time 17.163 s, sleep time 2.370 s,
      average rate 872.560715 MBps
```

`--archive-timeout=wait_time`

Sets the timeout for WAL segment archiving and streaming, in seconds. By default, `pg_probackup` waits 300 seconds.

`--skip-block-validation`

Disables block-level checksum verification to speed up the backup process.

`--no-validate`

Skips automatic validation after the backup is taken. You can use this flag if you validate backups regularly and would like to save time when running backup operations.

`--no-sync`

Do not sync backed up files to disk. You can use this flag to speed up the backup process. Using this flag can result in data corruption in case of operating system or hardware crash. If you use this option, it is recommended to run the [validate](#) command once the backup is complete to detect possible issues.

`--note=backup_note`

Sets the text note for backup copy. If `backup_note` contain newline characters, then only substring before first newline character will be saved. Max size of text note is 1 KB. The `'none'` value removes current note.

For more details of the command settings, see sections [Common Options](#), [Connection Options](#), [Retention Options](#), [Pinning Options](#), [Remote Mode Options](#), [Compression Options](#), and [Logging Options](#).

For details on usage, see the section [Creating a Backup](#).

restore

```
pg_probackup restore -B backup_dir --instance=instance_name
[--help] [--dry-run] [-D data_dir] [-i backup_id]
[-j num_threads] [--progress]
[-T OLDDIR=NEWDIR] [--external-mapping=OLDDIR=NEWDIR] [--skip-external-dirs]
[-R | --restore-as-replica] [--no-validate] [--skip-block-validation]
[--force] [--no-sync] [--allow-group-access]
[--restore-command=cmdline]
[--primary-conninfo=primary_conninfo]
[-S | --primary-slot-name=slot_name]
[-X wal_dir | --waldir=wal_dir]
[recovery_target_options] [logging_options] [remote_options]
[partial_restore_options] [remote_wal_archive_options]
```

Restores the Postgres Pro instance from a backup copy located in the `backup_dir` backup catalog. If you specify a [recovery target option](#), `pg_probackup` finds the closest backup and restores it to the specified recovery target. If neither the backup ID nor recovery target options are provided, `pg_probackup` uses the most recent backup to perform the recovery.

`-R`
`--restore-as-replica`

Creates a minimal recovery configuration file to facilitate setting up a standby server. If the replication connection requires a password, you must specify the password manually in the `primary_conninfo` parameter as it is not included. For Postgres Pro 11 or lower, recovery settings are written into the `recovery.conf` file. Starting from Postgres Pro 12, `pg_probackup` writes these settings into the `probackup_recovery.conf` file in the data directory, and then includes them into the `postgresql.auto.conf` when the cluster is started.

`--primary-conninfo=primary_conninfo`

Sets the `primary_conninfo` parameter to the specified value. This option will be ignored unless the `-R` flag is specified.

Example: `--primary-conninfo="host=192.168.1.50 port=5432 user=foo password=foopass"`

`-S`
`--primary-slot-name=slot_name`

Sets the `primary_slot_name` parameter to the specified value. This option will be ignored unless the `-R` flag is specified.

`-T OLDDIR=NEWDIR`
`--tablespace-mapping=OLDDIR=NEWDIR`

Relocates the tablespace from the `OLDDIR` to the `NEWDIR` directory at the time of recovery. Both `OLDDIR` and `NEWDIR` must be absolute paths. If the path contains the equals sign (=), escape it with a backslash. This option can be specified multiple times for multiple tablespaces.

`--external-mapping=OLDDIR=NEWDIR`

Relocates an external directory included into the backup from the `OLDDIR` to the `NEWDIR` directory at the time of recovery. Both `OLDDIR` and `NEWDIR` must be absolute paths. If the path contains the equals sign (=), escape it with a backslash. This option can be specified multiple times for multiple directories.

`--skip-external-dirs`

Skip external directories included into the backup with the `--external-dirs` option. The contents of these directories will not be restored.

`--skip-block-validation`

Disables block-level checksum verification to speed up validation. During automatic validation before the restore only file-level checksums will be verified.

`--no-validate`

Skips backup validation. You can use this flag if you validate backups regularly and would like to save time when running restore operations.

`--allow-group-access`

Provides any OS user in the same group as the cluster owner with the same access to the `PGDATA` directory on the database server as the cluster owner has. Running `restore` with this option will set the same permissions as when the cluster is created using the command

```
initdb --group access
```

`--restore-command=cmdline`

Sets the `restore_command` parameter to the specified command. For example: `--restore-command='cp /mnt/server/archivedir/%f "%p"'`

`--force`

Allows to ignore an invalid status of the backup. You can use this flag if you need to restore the Postgres Pro cluster from a corrupt or an invalid backup. Use with caution. If `PGDATA` contains a non-empty directory with system ID different from that of the backup being restored, [incremental restore](#) with this flag overwrites the directory contents (while an error occurs without the flag). If tablespaces are remapped through the `--tablespace-mapping` option into non-empty directories, the contents of such directories will be deleted.

`--no-sync`

Do not sync restored files to disk. You can use this flag to speed up restore process. Using this flag can result in data corruption in case of operating system or hardware crash. If it happens, you have to run the [restore](#) command again.

`-X wal_dir`

`--waldir=wal_dir`

Sets the directory to write WAL files to. By default WAL files will be placed in the `pg_wal` subdirectory of the target directory, but this option can be used to place them elsewhere. `wal_dir` must be an absolute path, which must not already exist, but if it does, it must be empty.

For more details of the command settings, see sections [Common Options](#), [Recovery Target Options](#), [Remote Mode Options](#), [Remote WAL Archive Options](#), [Logging Options](#), and [Partial Restore Options](#).

For details on usage, see the section [Restoring a Cluster](#).

checkdb

`pg_probackup checkdb`

`[-B backup_dir] [--instance=instance_name] [-D data_dir]`

`[--help] [-j num_threads] [--progress]`

`[--amcheck [--skip-block-validation] [--checkunique] [--heapallindexed]]`

`[connection_options] [logging_options]`

Verifies the Postgres Pro database cluster correctness by detecting physical and logical corruption.

`--amcheck`

Performs logical verification of indexes for the specified Postgres Pro instance if no corruption was found while checking data files. You must have the [amcheck](#) extension or the `amcheck_next` extension installed in the database to check its indexes. For databases without `amcheck`, index verification will be skipped. Additional options `--checkunique` and `--heapallindexed` are effective depending on the version of `amcheck` installed.

`--checkunique`

Verifies unique constraints during logical verification of indexes. You can use this flag only together with the `--amcheck` flag when the `amcheck` extension is installed in the database.

The verification of unique constraints is only possible if in the version of the `amcheck` extension you are using, the `bt_index_check` function takes the `checkunique` parameter.

`--heapallindexed`

Checks that all heap tuples that should be indexed are actually indexed. You can use this flag only together with the `--amcheck` flag.

This check is only possible if in the version of the `amcheck/amcheck_next` extension you are using, the `bt_index_check` function takes the `heapallindexed` parameter.

`--skip-block-validation`

Skip validation of data files. You can use this flag only together with the `--amcheck` flag, so that only logical verification of indexes is performed.

For more details of the command settings, see sections [Common Options](#), [Connection Options](#), and [Logging Options](#).

For details on usage, see the section [Verifying a Cluster](#).

validate

```
pg_probackup validate -B backup_dir
[--help] [--instance=instance_name] [-i backup_id]
[-j num_threads] [--progress] [--wal]
[--skip-block-validation]
[recovery_target_options] [logging_options]
```

Verifies that all the files required to restore the cluster are present and are not corrupt. If *instance_name* is not specified, pg_probackup validates all backups available in the backup catalog. If you specify the *instance_name* without any additional options, pg_probackup validates all the backups available for this backup instance. If you specify the *instance_name* with a [recovery target option](#) and/or a *backup_id*, pg_probackup checks whether it is possible to restore the cluster using these options. If the `--wal` option is specified, full check of the WAL archive will be performed instead of only checking WAL segments needed to restore the cluster.

For details, see the section [Validating a Backup](#).

merge

```
pg_probackup merge -B backup_dir --instance=instance_name -i backup_id
[--dry-run] [--help] [-j num_threads] [--progress] [--no-validate] [--no-sync]
[logging_options]
```

Merges backups that belong to a common incremental backup chain. If you specify a full backup, it will be merged with its first incremental backup. If you specify an incremental backup, it will be merged to its parent full backup, together with all incremental backups between them. Once the merge is complete, the full backup takes in all the merged data, and the incremental backups are removed as redundant.

`--no-validate`

Skips automatic validation before and after merge.

`--no-sync`

Do not sync merged files to disk. You can use this flag to speed up the merge process. Using this flag can result in data corruption in case of operating system or hardware crash.

For more details of the command settings, see sections [Common Options](#) and [Merging Backups](#).

delete

```
pg_probackup delete -B backup_dir --instance=instance_name
[--help] [-j num_threads] [--progress]
[--retention-redundancy=redundancy] [--retention-window=window] [--wal-depth=wal_depth]
[--delete-wal]
{-i backup_id | --delete-expired [--merge-expired] | --merge-expired | --
status=backup_status}
[--dry-run] [--no-validate] [--no-sync] [logging_options]
```

Deletes backup with specified *backup_id* or launches the retention purge of backups and archived WAL that do not satisfy the current retention policies.

`--no-validate`

Skips automatic validation before and after retention merge.

`--no-sync`

Do not sync merged files to disk. You can use this flag to speed up the retention merge process. Using this flag can result in data corruption in case of operating system or hardware crash.

For details, see the sections [Deleting Backups](#), [Retention Options](#), and [Configuring Retention Policy](#).

archive-push

```
pg_probackup archive-push -B backup_dir --instance=instance_name
--wal-file-name=wal_file_name [--wal-file-path=wal_file_path]
[--help] [--dry-run] [--no-sync] [--compress] [--no-ready-rename] [--overwrite]
[-j num_threads] [--batch-size=batch_size]
[--archive-timeout=timeout]
[--compress-algorithm=compression_algorithm]
[--compress-level=compression_level]
[remote_options] [logging_options]
```

Copies WAL files into the corresponding subdirectory of the backup catalog and validates the backup instance by *instance_name* and system-identifier. If parameters of the backup instance and the cluster do not match, this command fails with the following error message: Refuse to push WAL segment *segment_name* into archive. Instance parameters mismatch.

If the files to be copied already exists in the backup catalog, `pg_probackup` computes and compares their checksums. If the checksums match, `archive-push` skips the corresponding file and returns a successful execution code. Otherwise, `archive-push` fails with an error. If you would like to replace WAL files in the case of checksum mismatch, run the `archive-push` command with the `--overwrite` flag.

Each file is copied to a temporary file with the `.part` suffix. If the temporary file already exists, `pg_probackup` will wait `archive_timeout` seconds before discarding it. After the copy is done, atomic rename is performed. This algorithm ensures that a failed `archive-push` will not stall continuous archiving and that concurrent archiving from multiple sources into a single WAL archive has no risk of archive corruption.

The Postgres Pro server requests WAL segments one at a time. To speed up archiving, you can specify the `--batch-size` option to copy WAL segments in batches of the specified size. If `--batch-size` option is used, then you can also specify the `-j` option to copy the batch of WAL segments on multiple threads.

WAL segments copied to the archive are synced to disk unless the `--no-sync` flag is used.

You can use `archive-push` in the [archive_command](#) Postgres Pro parameter to set up [continuous WAL archiving](#).

For more details of the command settings, see sections [Common Options](#), [Archiving Options](#), and [Compression Options](#).

archive-get

```
pg_probackup archive-get -B backup_dir --instance=instance_name --wal-file-
path=wal_file_path --wal-file-name=wal_file_name
[-j num_threads] [--batch-size=batch_size]
[--prefetch-dir=prefetch_dir_path] [--no-validate-wal]
[--dry-run] [--help] [remote_options] [logging_options]
```

Copies WAL files from the corresponding subdirectory of the backup catalog to the cluster's write-ahead log location. This command is automatically set by `pg_probackup` as part of the `restore_command` when restoring backups using a WAL archive. You do not need to set it manually.

The Postgres Pro server requests WAL segments one at a time. To speed up recovery, you can specify the `--batch-size` option to copy WAL segments in batches of the specified size. If `--batch-size` option is used, then you can also specify the `-j` option to copy the batch of WAL segments on multiple threads.

For more details of the command settings, see sections [Common Options](#), [Archiving Options](#), and [Compression Options](#).

catchup

```
pg_probackup catchup -b catchup_mode
```

```
--source-pgdata=path_to_pgdata_on_remote_server
--destination-pgdata=path_to_local_dir
[--help] [-j | --threads=num_threads] [--dry-run]
[--write-rate-limit=bitrate]
[--stream [--temp-slot[=true|false|on|off]] [-P | --perm-slot] [-S | --slot=slot_name]]
[--exclude-path=PATHNAME]
[-T OLDDIR=NEWDIR]
[-X | --waldir=wal_dir]
[connection_options] [remote_options]
[logging_options]
```

Creates a copy of a Postgres Pro instance without using the backup catalog.

```
-b catchup_mode
--backup-mode=catchup_mode
```

Specifies the catchup mode to use. Possible values are: [FULL](#), [DELTA](#), and [PTRACK](#).

```
--source-pgdata=path_to_pgdata_on_remote_server
```

Specifies the path to the data directory of the instance to be copied. The path can be local or remote.

```
--destination-pgdata=path_to_local_dir
```

Specifies the path to the local data directory to copy to.

```
-j num_threads
--threads=num_threads
```

Sets the number of parallel threads for `catchup` process.

```
--stream
```

Copies the instance in [STREAM](#) WAL delivery mode, including all the necessary WAL files by streaming them from the server via replication protocol. For `catchup`, it is enabled by default.

```
--write-rate-limit=bitrate
```

Sets the rate of writing data to disk, in MBps or GBps. The default unit is MBps. For example: `--write-rate-limit=1GBps` or `--write-rate-limit=100` (MBps). The default value is 0 — no limitation.

If this option is specified, the following information is displayed at the end of the `catchup` operation:

- `written` — the amount of data written, in MB.
- `total time` — the time that elapsed between the first and last writes, in seconds. Note that this is not the total duration of the `catchup` operation.
- `sleep time` — the amount of forced delay time, in seconds.
- `average rate` — the actual average write rate, in MBps.

For example:

```
INFO: Rate limit: written 14975.445 MB, total time 17.163 s, sleep time 2.370 s,
      average rate 872.560715 MBps
```

```
-x=path_prefix
--exclude-path=path_prefix
```

Specifies a prefix for files to exclude from the synchronization of Postgres Pro instances during copying. The prefix must contain a path relative to the data directory of an instance. If the prefix specifies a directory, all files in this directory will not be synchronized.

Warning

This option is dangerous since excluding files from synchronization can result in incomplete synchronization; use with care.

`--temp-slot [=true|false|on|off]`

Creates a *temporary* physical replication slot for streaming WAL from the Postgres Pro instance being copied. `--temp-slot` is enabled by default. It ensures that all the required WAL segments remain available if WAL is rotated while the backup is in progress. This flag can only be used together with the `--stream` flag and cannot be used together with the `--perm-slot` flag. The default slot name is `pg_probackup_slot`. To change it, use the `--slot/-S` option and explicitly specify `--temp-slot` or `--temp-slot=true|on`.

`-P`

`--perm-slot`

Creates a *permanent* physical replication slot for streaming WAL from the Postgres Pro instance being copied. This flag can only be used together with the `--stream` flag and cannot be used together with the `--temp-slot` flag. The default slot name is `pg_probackup_perm_slot`, which can be changed using the `--slot/-S` option.

`-S slot_name`

`--slot=slot_name`

Specifies the replication slot to connect to for WAL streaming. This option can only be used together with the `--stream` flag.

`-T OLDDIR=NEWDIR`

`--tablespace-mapping=OLDDIR=NEWDIR`

Relocates the tablespace from the *OLDDIR* to the *NEWDIR* directory at the time of recovery. Both *OLDDIR* and *NEWDIR* must be absolute paths. If the path contains the equals sign (=), escape it with a backslash. This option can be specified multiple times for multiple tablespaces.

`-X wal_dir`

`--waldir=wal_dir`

Sets the directory to write WAL files to. By default WAL files will be placed in the `pg_wal` subdirectory of the target directory, but this option can be used to place them elsewhere. *wal_dir* must be an absolute path, which must not already exist, but if it does, it must be empty to perform `catchup` with `--catchup-mode=FULL`.

For more details of the command settings, see sections [Common Options](#), [Connection Options](#), and [Remote Mode Options](#).

For details on usage, see the section [Cloning and Synchronizing Postgres Pro Instance](#).

maintain

```
pg_probackup maintain --B backup_dir --instance=instance_name
[-i backup_id] --status-sync [--help] [--dry-run]
[--log-level-console=log-level-console] [--log-level-file=log-level-file]
[--log-format-console=log-format-console] [--log-format-file=log-format-file]
[--log-filename=log-filename]
```

Performs a cleanup of the directory with backups of the specified instance after a forced termination of previous `pg_probackup` commands.

`--status-sync`

Detects expired locks and hanging backups, as well as updates backup statuses.

For more details of the command settings, see sections [Common Options](#) and [Logging Options](#).

Options

This section describes command-line options for `pg_probackup` commands. If the option value can be derived from an environment variable, this variable is specified below the command-line option, in the uppercase. Some values can be taken from the `pg_probackup.conf` configuration file located in the backup catalog.

For details, see [the section called “Configuring pg_probackup”](#).

If an option is specified using more than one method, command-line input has the highest priority, while the `pg_probackup.conf` settings have the lowest priority.

Common Options

The list of general options.

`--dry-run`

Initiates a trial run of the appropriate command, which does not actually do any changes, that is, it does not create, delete or move files on disk. This flag allows you to check that all the command options are correct and the command is ready to run. WAL streaming is skipped with `--dry-run`.

`-B directory`

`--backup-path=directory`

`BACKUP_PATH`

Specifies the absolute path to the backup catalog. Backup catalog is a directory where all backup files and meta information are stored. Since this option is required for most of the `pg_probackup` commands, you are recommended to specify it once in the `BACKUP_PATH` environment variable. In this case, you do not need to use this option each time on the command line.

`-D directory`

`--pgdata=directory`

`PGDATA`

Specifies the absolute path to the data directory of the database cluster. This option is mandatory only for the [add-instance](#) command. Other commands can take its value from the `PGDATA` environment variable, or from the `pg_probackup.conf` configuration file.

`-i backup_id`

`--backup-id=backup_id`

Specifies the unique identifier of the backup.

`--instance instance_name`

Specifies the name of the Postgres Pro instance.

`-j num_threads`

`--threads=num_threads`

Sets the number of parallel threads for backup, restore, merge, validate, checkdb, and archive-push processes.

`--progress`

Shows the progress of operations.

`--help`

Shows detailed information about the options that can be used with this command.

Recovery Target Options

If [continuous WAL archiving](#) is configured, you can use one of these options together with [restore](#) or [validate](#) commands to specify the moment up to which the database cluster must be restored or validated.

`--recovery-target=immediate|latest`

Defines when to stop the recovery:

- The `immediate` value stops the recovery after reaching the consistent state of the specified backup, or the latest available backup if the `-i/--backup-id` option is omitted. This is the default behavior for STREAM backups.
- The `latest` value continues the recovery until all WAL segments available in the archive are applied. Setting this value of `--recovery-target` also sets `--recovery-target-timeline` to `latest`.

`--recovery-target-timeline=timeline`

Specifies a particular timeline to be used for recovery:

- `current` — the timeline of the specified backup, default.
- `latest` — the timeline of the latest available backup.
- A numeric value.

`--recovery-target-lsn=lsn`

Specifies the LSN of the write-ahead log location up to which recovery will proceed.

`--recovery-target-name=recovery_target_name`

Specifies a named savepoint up to which to restore the cluster.

`--recovery-target-time=time`

Specifies the timestamp up to which recovery will proceed. If the time zone offset is not specified, the local time zone is used.

Example: `--recovery-target-time="2027-04-09 18:21:32+00"`

`--recovery-target-xid=xid`

Specifies the transaction ID up to which recovery will proceed.

`--recovery-target-inclusive=boolean`

Specifies whether to stop just after the specified recovery target (`true`), or just before the recovery target (`false`). This option can only be used together with `--recovery-target-time`, `--recovery-target-lsn` or `--recovery-target-xid` options. The default depends on the [recovery_target_inclusive](#) parameter.

`--recovery-target-action=pause|promote|shutdown`

Specifies [recovery_target_action](#) the server should take when the recovery target is reached.

Default: `pause`

Retention Options

You can use these options together with [backup](#) and [delete](#) commands.

For details on configuring retention policy, see the section [Configuring Retention Policy](#).

`--retention-redundancy=redundancy`

Specifies the number of full backup copies to keep in the data directory. Must be a non-negative integer. The zero value disables this setting.

Default: 0

`--retention-window=window`

Number of days of recoverability. Must be a non-negative integer. The zero value disables this setting.

Default: 0

`--wal-depth=wal_depth`

Number of latest valid backups on every timeline that must retain the ability to perform PITR. Must be a non-negative integer. The zero value disables this setting.

Default: 0

`--delete-wal`

Deletes WAL files that are no longer required to restore the cluster from any of the existing backups.

`--delete-expired`

Deletes backups that do not conform to the retention policy defined in the `pg_probackup.conf` configuration file.

`--merge-expired`

Merges the oldest incremental backup that satisfies the requirements of retention policy with its parent backups that have already expired.

`--dry-run`

Displays the current status of all the available backups, without deleting or merging expired backups, if any.

Pinning Options

You can use these options together with [backup](#) and [set-backup](#) commands.

For details on backup pinning, see the section [Backup Pinning](#).

`--ttl=ttl`

Specifies the amount of time the backup should be pinned. Must be a non-negative integer. The zero value unpins the already pinned backup. Supported units: ms, s, min, h, d (s by default).

Example: `--ttl=30d`

`--expire-time=time`

Specifies the timestamp up to which the backup will stay pinned. Must be an ISO-8601 compliant timestamp. If the time zone offset is not specified, the local time zone is used.

Example: `--expire-time="2027-04-09 18:21:32+00"`

Logging Options

You can use these options with any command.

`--no-color`

Disable coloring for console log messages of warning and error levels.

`--log-level-console=log_level`

Controls which message levels are sent to the console log. Valid values are `verbose`, `log`, `info`, `warning`, `error` and `off`. Each level includes all the levels that follow it. The later the level, the fewer messages are sent. The `off` level disables console logging.

Default: `info`

Note

All console log messages are going to stderr, so the output of [show](#) and [show-config](#) commands does not mingle with log messages.

`--log-level-file=log_level`

Controls which message levels are sent to a log file. Valid values are `verbose`, `log`, `info`, `warning`, `error`, and `off`. Each level includes all the levels that follow it. The later the level, the fewer messages are sent. The `off` level disables file logging.

Default: `off`

`--log-filename=log_filename`

Defines the filenames of the created log files. The filenames are treated as a `strftime` pattern, so you can use %-escapes to specify time-varying filenames.

Default: `pg_probackup.log`

For example, if you specify the `pg_probackup-%u.log` pattern, `pg_probackup` generates a separate log file for each day of the week, with `%u` replaced by the corresponding decimal number: `pg_probackup-1.log` for Monday, `pg_probackup-2.log` for Tuesday, and so on.

This option takes effect if file logging is enabled by the `--log-level-file` option.

`--error-log-filename=error_log_filename`

Defines the filenames of log files for error messages only. The filenames are treated as a `strftime` pattern, so you can use %-escapes to specify time-varying filenames.

Default: `none`

For example, if you specify the `error-pg_probackup-%u.log` pattern, `pg_probackup` generates a separate log file for each day of the week, with `%u` replaced by the corresponding decimal number: `error-pg_probackup-1.log` for Monday, `error-pg_probackup-2.log` for Tuesday, and so on.

This option is useful for troubleshooting and monitoring.

`--log-directory=log_directory`

Defines the directory in which log files will be created. You must specify the absolute path. This directory is created lazily, when the first log message is written.

Default: `$BACKUP_PATH/log/`

`--log-format-console=log_format`

Defines the format of the console log. Only set from the command line. Note that you cannot specify this option in the `pg_probackup.conf` configuration file through the [set-config](#) command and that the [backup](#) command also treats this option specified in the configuration file as an error. Possible values are:

- `plain` — sets the plain-text format of the console log.
- `json` — sets the JSON format of the console log.

Default: `plain`

`--log-format-file=log_format`

Defines the format of log files used. Possible values are:

- `plain` — sets the plain-text format of log files.
- `json` — sets the JSON format of log files.

Default: plain

`--log-rotation-size=log_rotation_size`

Maximum size of an individual log file. If this value is reached, the log file is rotated once a `pg_probackup` command is launched, except `help` and `version` commands. The zero value disables size-based rotation. Supported units: kB, MB, GB, TB (kB by default).

Default: 0

`--log-rotation-age=log_rotation_age`

Maximum lifetime of an individual log file. If this value is reached, the log file is rotated once a `pg_probackup` command is launched, except `help` and `version` commands. The time of the last log file creation is stored in `$BACKUP_PATH/log/log_rotation`. The zero value disables time-based rotation. Supported units: ms, s, min, h, d (min by default).

Default: 0

Connection Options

You can use these options together with `backup`, `catchup`, and `checkdb` commands.

All `libpq` environment variables are supported.

`-d dbname`

`--pgdatabase=dbname`

`PGDATABASE`

Specifies the name of the database to connect to. The connection is used only for managing backup process, so you can connect to any existing database. If this option is not provided on the command line, `PGDATABASE` environment variable, or the `pg_probackup.conf` configuration file, `pg_probackup` tries to take this value from the `PGUSER` environment variable, or from the current user name if `PGUSER` variable is not set.

`-h host`

`--pghost=host`

`PGHOST`

Specifies the host name of the system on which the server is running. If the value begins with a slash, it is used as a directory for the Unix domain socket.

Default: localhost

`-p port`

`--pgport=port`

`PGPORT`

Specifies the TCP port or the local Unix domain socket file extension on which the server is listening for connections.

Default: 5432

`-U username`

`--pguser=username`

`PGUSER`

User name to connect as.

`-w`

`--no-password`

Disables a password prompt. If the server requires password authentication and a password is not available by other means such as a `.pgpass` file or `PGPASSWORD` environment variable, the connection

attempt will fail. This flag can be useful in batch jobs and scripts where no user is present to enter a password.

`-W`

`--password`

Forces a password prompt. (Deprecated)

Compression Options

You can use these options together with [backup](#) and [archive-push](#) commands.

`--compress-algorithm=compression_algorithm`

Defines the algorithm to use for compressing data files. Possible values are `zlib`, `lz4`, `zstd`, `pglz`, and `none`. If set to any value, but `none`, this option enables compression that uses the corresponding algorithm. Both data files and WAL files are compressed. By default, compression is disabled. For the [archive-push](#) command, the `pglz` compression algorithm is not supported.

Note

`pg_probackup` supports compression algorithms included in the Postgres Pro version. In particular:

- `lz4` is supported for Postgres Pro 14 and higher.
- `zstd` is supported for Postgres Pro 15 and higher.

Default: `none`

`--compress-level=compression_level`

Defines the compression level. This option can be used together with the `--compress-algorithm` option. Possible values depend on the compression algorithm specified:

- 0 — 9 for `zlib`
- 1 for `pglz`
- 0 — 12 for `lz4`
- -131072 — 22 for `zstd`

The value of 0 sets the default compression level, which is 1, for all compression algorithms.

Note

The pure `lz4` algorithm has only one compression level — 1. So, if the specified compression algorithm is `lz4` and `--compress-level` is greater than 1, the `lz4hc` algorithm is actually used, which is much slower although does better compression.

Default: 1

`--compress`

Specifies the default compression algorithm and `--compress-level=1`. The default algorithm is selected among those supported by Postgres Pro according to the priorities: `zstd` (highest) -> `lz4` -> `zlib` -> `pglz`. The `--compress` option overrides the `--compression-algorithm` and `--compress-level` settings and cannot be specified together with them.

Archiving Options

These options can be used with the [archive-push](#) command in the `archive_command` setting and the [archive-get](#) command in the `restore_command` setting.

Additionally, [remote mode options](#) and [logging options](#) can be used.

`--wal-file-path=wal_file_path`

Provides the path to the WAL file in *archive_command* and *restore_command*. Use the `%p` variable as the value for this option or explicitly specify the path to a file outside of the data directory. If you skip this option, the path specified in `pg_probackup.conf` will be used.

`--wal-file-name=wal_file_name`

Provides the name of the WAL file in *archive_command* and *restore_command*. Use the `%f` variable as the value for this option for correct processing. If the value of `--wal-file-path` is a path outside of the data directory, explicitly specify the filename.

`--overwrite`

Overwrites archived WAL file. Use this flag together with the [archive-push](#) command if the specified subdirectory of the backup catalog already contains this WAL file and it needs to be replaced with its newer copy. Otherwise, `archive-push` reports that a WAL segment already exists, and aborts the operation. If the file to replace has not changed, `archive-push` skips this file regardless of the `--overwrite` flag.

`--batch-size=batch_size`

Used to speed up archiving in case of `archive-push` or to speed up recovery in case of `archive-get`. Sets the maximum number of WAL files that can be copied into the archive by a single `archive-push` process, or from the archive by a single `archive-get` process.

`--archive-timeout=wait_time`

Sets the timeout for considering existing `.part` files to be stale. By default, `pg_probackup` waits 300 seconds. This option can be used only with [archive-push](#) command.

`--no-ready-rename`

Do not rename status files in the `archive_status` directory. This option should be used only if *archive_command* contains multiple commands. This option can be used only with [archive-push](#) command.

`--no-sync`

Do not sync copied WAL files to disk. You can use this flag to speed up archiving process. Using this flag can result in WAL archive corruption in case of operating system or hardware crash. This option can be used only with [archive-push](#) command.

`--prefetch-dir=path`

Directory used to store prefetched WAL segments if `--batch-size` option is used. Directory must be located on the same filesystem and on the same mountpoint the `PGDATA/pg_wal` is located. By default files are stored in `PGDATA/pg_wal/pbk_prefetch` directory. This option can be used only with [archive-get](#) command.

`--no-validate-wal`

Do not validate prefetched WAL file before using it. Use this option if you want to increase the speed of recovery. This option can be used only with [archive-get](#) command.

Remote Mode Options

This section describes the options related to running `pg_probackup` operations remotely via SSH. These options can be used with [add-instance](#), [set-config](#), [backup](#), [catchup](#), [restore](#), [archive-push](#), and [archive-get](#) commands.

For details on configuring and using the remote mode, see [the section called “Configuring the Remote Mode”](#) and [the section called “Using pg_probackup in the Remote Mode”](#).

`--remote-proto=proto`

Specifies the protocol to use for remote operations. Currently only the SSH protocol is supported. Possible values are:

- `ssh` enables the remote mode via SSH. This is the default value.
- `none` explicitly disables the remote mode.

You can omit this option if the `--remote-host` option is specified.

`--remote-host=destination`

Specifies the remote host IP address or hostname to connect to.

`--remote-port=port`

Specifies the remote host port to connect to.

Default: 22

`--remote-user=username`

Specifies remote host user for SSH connection. If you omit this option, the current user initiating the SSH connection is used.

`--remote-path=path`

Specifies `pg_probackup` installation directory on the remote system.

`--ssh-options=ssh_options`

Provides a string of SSH command-line options. For example, the following options can be used to set `keep-alive` for SSH connections opened by `pg_probackup`: `--ssh-options="-o ServerAliveCountMax=5 -o ServerAliveInterval=60"`. For the full list of possible options, see [ssh_config manual page](#).

Remote WAL Archive Options

This section describes the options used to provide the arguments for [remote mode options](#) in `archive-get` used in the `restore_command` command when restoring ARCHIVE backups or performing PITR.

`--archive-host=destination`

Provides the argument for the `--remote-host` option in the `archive-get` command.

`--archive-port=port`

Provides the argument for the `--remote-port` option in the `archive-get` command.

Default: 22

`--archive-user=username`

Provides the argument for the `--remote-user` option in the `archive-get` command. If you omit this option, the user that has started the Postgres Pro cluster is used.

Default: Postgres Pro user

Incremental Restore Options

This section describes the options for incremental cluster restore. These options can be used with the `restore` command.

`-I incremental_mode`

`--incremental-mode=incremental_mode`

Specifies the incremental mode to be used. Possible values are:

- `CHECKSUM` — replace only pages with mismatched checksum and LSN.
- `LSN` — replace only pages with LSN greater than point of divergence.
- `NONE` — regular restore.

Partial Restore Options

This section describes the options for partial cluster restore. These options can be used with the [restore](#) command.

`--db-exclude=dbname`

Specifies the name of the database to exclude from restore. All other databases in the cluster will be restored as usual, including `template0` and `template1`. This option can be specified multiple times for multiple databases.

`--db-include=dbname`

Specifies the name of the database to restore from a backup. All other databases in the cluster will not be restored, with the exception of `template0` and `template1`. This option can be specified multiple times for multiple databases.

Testing and Debugging Options

This section describes options useful only in a test or development environment.

`PGPROBACKUP_TESTS_SKIP_HIDDEN`

Instructs `pg_probackup` to ignore backups marked as hidden. Note that `pg_probackup` can never mark a backup as hidden. It can only be done by directly editing the `backup.control` file. This option can only be set with environment variables.

`--destroy-all-other-dbs`

By default, `pg_probackup` exits with an error if an attempt is made to perform a partial incremental restore since this destroys databases not included in the restore set. This flag allows you to suppress the error and proceed with the partial incremental restore (e.g., to keep a development database snapshot up-to-date with a production one). This option can be used with the [restore](#) command.

Important

Never use this flag in a production cluster.

`--lock-lifetime`

Specifies the lifetime for locks taken when performing a backup, in seconds. The default value is 300. The minimum value is 60.

`PGPROBACKUP_TESTS_SKIP_EMPTY_COMMIT`

Instructs `pg_probackup` to skip empty commits after `pg_backup_stop`.

Versioning

`pg_probackup` follows [semantic](#) versioning.

Authors

Postgres Professional, Moscow, Russia.

Credits

`pg_probackup` utility is based on `pg_arman`, which was originally written by NTT and then developed and maintained by Michael Paquier.

vacuumlo

`vacuumlo` — remove orphaned large objects from a Postgres Pro database

Synopsis

```
vacuumlo [option...] dbname...
```

Description

`vacuumlo` is a simple utility program that will remove any “orphaned” large objects from a Postgres Pro database. An orphaned large object (LO) is considered to be any LO whose OID does not appear in any `oid` or `lo` data column of the database.

If you use this, you may also be interested in the `lo_manage` trigger in the [lo](#) module. `lo_manage` is useful to try to avoid creating orphaned LOs in the first place.

All databases named on the command line are processed.

Options

`vacuumlo` accepts the following command-line arguments:

```
-l limit  
--limit=limit
```

Remove no more than *limit* large objects per transaction (default 1000). Since the server acquires a lock per LO removed, removing too many LOs in one transaction risks exceeding [max_locks_per_transaction](#). Set the limit to zero if you want all removals done in a single transaction.

```
-n  
--dry-run
```

Don't remove anything, just show what would be done.

```
-v  
--verbose
```

Write a lot of progress messages.

```
-V  
--version
```

Print the `vacuumlo` version and exit.

```
-?  
--help
```

Show help about `vacuumlo` command line arguments, and exit.

`vacuumlo` also accepts the following command-line arguments for connection parameters:

```
-h host  
--host=host
```

Database server's host.

```
-p port  
--port=port
```

Database server's port.

```
-U username  
--username=username
```

User name to connect as.

```
-w  
--no-password
```

Never issue a password prompt. If the server requires password authentication and a password is not available by other means such as a `.pgpass` file, the connection attempt will fail. This option can be useful in batch jobs and scripts where no user is present to enter a password.

```
-W  
--password
```

Force vacuumlo to prompt for a password before connecting to a database.

This option is never essential, since vacuumlo will automatically prompt for a password if the server demands password authentication. However, vacuumlo will waste a connection attempt finding out that the server wants a password. In some cases it is worth typing `-w` to avoid the extra connection attempt.

Environment

```
PGHOST  
PGPORT  
PGUSER
```

Default connection parameters.

This utility, like most other Postgres Pro utilities, also uses the environment variables supported by libpq (see [Section 33.15](#)).

The environment variable `PG_COLOR` specifies whether to use color in diagnostic messages. Possible values are `always`, `auto` and `never`.

Notes

vacuumlo works by the following method: First, vacuumlo builds a temporary table which contains all of the OIDs of the large objects in the selected database. It then scans through all columns in the database that are of type `oid` or `lo`, and removes matching entries from the temporary table. (Note: Only types with these names are considered; in particular, domains over them are not considered.) The remaining entries in the temporary table identify orphaned LOs. These are removed.

Author

Peter Mount <peter@retep.org.uk>

I.2. Third-Party Client Applications

This section covers third-party client applications included in the Postgres Pro Standard distribution. They can be run from anywhere, independent of where the database server resides. Note also that the `odbc` driver is available (see [Table 16.3](#) for details).

ldap2pg

ldap2pg — automate the creation, update, and removal of Postgres Pro roles and users from an enterprise directory

Synopsis

```
ldap2pg [option...] [dbname]
```

Description

Out of the box, Postgres Pro is able to check password of an existing role using the LDAP protocol. ldap2pg automates the creation, update and removal of Postgres Pro roles, and users from an enterprise directory.

Managing roles is close to managing privileges as you expect roles to have proper default privileges. Postgres Pro can grant and revoke privileges too.

ldap2pg is provided with Postgres Pro Standard as a separate pre-built package `ldap2pg` (for the detailed installation instructions, see [Chapter 16](#)).

ldap2pg is reported to work with [Samba DC](#), [OpenLDAP](#), [FreeIPA](#), Oracle Internet Directory and Microsoft Active Directory.

ldap2pg **requires** a configuration file called `ldap2pg.yaml`.

Features

- Reads settings from an expressive YAML config file.
- Creates, alters and drops Postgres Pro roles from LDAP searches.
- Creates static roles from YAML to complete LDAP entries.
- Manages role parents (alias *groups*).
- Grants or revokes privileges statically or from LDAP entries.
- Dry run, check mode.
- Logs LDAP searches as `ldapsearch(1)` commands.
- Logs **every** SQL statements.

Requirements

ldap2pg is released as a single binary with no dependencies.

At run time, ldap2pg requires an unprivileged role with `CREATEDB` and `CREATEROLE` options or a superuser access.

ldap2pg does not require to run on the same host as the synchronized Postgres Pro Standard cluster.

With 2MiB of RAM and one vCPU, ldap2pg can synchronize several thousands of roles in seconds, depending on Postgres Pro Standard instance and LDAP directory response time.

Command-Line Reference

ldap2pg tries to be friendly regarding configuration and consistent with `psql`, `OpenLDAP` utils and [The Twelve-Factor App](#). ldap2pg reads its configuration from several sources, in the following order, first prevail:

1. Command-line arguments.
2. Environment variables.
3. Configuration file.
4. `ldaprc`, `ldap.conf`, etc.

The command-line usage is as follows:

```
ldap2pg [OPTIONS] [dbname]
```

Where options are as follows:

`--check`
Check mode: exits with 1 if Postgres Pro instance is unsynchronized.

`--color`
Force color output.

`-c string`
`--config string`
Path to YAML configuration file. Use - for stdin.

`--directory string`
Path to directory containing configuration files.

`--help`
Show help message and exit (default true).

`--ldappassword-file string`
Path to LDAP password file.

`--quiet count`
Decrease log verbosity.

`--real`
Real mode. Apply changes to Postgres Pro instance.

`-skip-privileges`
Turn off privilege synchronization.

`--verbose count`
Increase log verbosity.

`--version`
Show version and exit (default true).

Optional argument `dbname` is alternatively the database name or a `conninfo` string or a URI. See `psql(1)` man page for more information.

By default, `ldap2pg` runs in dry mode. `ldap2pg` requires a configuration file to describe LDAP searches and mappings.

Arguments can be defined multiple times. On conflict, the last argument is used.

Environment Variables

`ldap2pg` has no command-line interface switch to configure Postgres Pro connection. However, `ldap2pg` supports [libpq PG* environment variables](#).

See [psql\(1\)](#) for details on `libpq` environment variables.

The same goes for LDAP, `ldap2pg` supports standard `LDAP*` environment variables and `.ldaprc` files. See `ldap.conf(5)` man page for further details on how to configure. `ldap2pg` accepts two extra variables: `LDAPPASSWORD` and `LDAPPASSWORD_FILE`.

`ldap2pg` loads `.env` file in the `lda2pg.yml`'s parent directory if exists.

Use `true` or `false` for boolean values in environment, e.g. `LDAP2PG_SKIPPRIVILEGES=true`.

Tip

Test Postgres Pro connection using `psql(1)` and LDAP using `ldapwhoami(1)` man pages, `ldap2pg` will be okay and it will be easier to debug the setup and the configuration later.

Logging Setup

`ldap2pg` has several levels of logging:

- **ERROR:** error details. When this happens, `ldap2pg` will crash.
- **WARNING:** `ldap2pg` warns about choices you should be aware of.
- **CHANGE:** only changes applied to Postgres Pro> cluster.
- **INFO (default):** tells what `ldap2pg` is doing, especially before long task.
- **DEBUG:** everything, including raw SQL queries and LDAP searches and introspection details.

The `--quiet` and `--verbose` command-line switches respectively decrease and increase verbosity.

You can select the highest level of verbosity with `LDAP2PG_VERBOSITY` environment variable. For example:

```
$ LDAP2PG_VERBOSITY=DEBUG ldap2pg
12:23:45 INFO    Starting ldap2pg                                version=v6.0-alpha5
runtime=go1.21.0 commit=<none>
12:23:45 WARN    Running a prerelease! Use at your own risks!
12:23:45 DEBUG   Searching configuration file in standard locations.
12:23:45 DEBUG   Found configuration file.                        path=./ldap2pg.yml
$
```

`ldap2pg` output varies whether it is running with a TTY or not. If standard error is a TTY, logging is colored and tweaked for human reading. Otherwise, logging format is pure logfmt, for machine processing. You can force human-readable output by using `--color` command-line interface switch.

ldap2pg.yml File Reference

`ldap2pg` requires a YAML configuration file usually named `ldap2pg.yml` and put in working directory. Everything can be configured from the YAML file: Postgres Pro inspect queries, LDAP searches, privileges and synchronization map.

Warning

`ldap2pg` *requires* a configuration file where the synchronization map is described.

Here are the contents of a tested `ldap2pg.yml`, which can be used as a starting point:

```
#
#
#      L D A P 2 P G      S A M P L E      C O N F I G U R A T I O N
#
# This is a starting point configuration file for ldap2pg.yml. Including static
# roles, groups, privilege and LDAP search.
#
# This configuration assumes the following principles:
#
# - All LDAP users are grouped in `ldap_roles` group.
# - Read privileges are granted to `readers` group.
# - Write privileges are granted to `writers` group.
# - DDL privileges are granted to `owners` group.
# - We have one or more databases with public and maybe a schema.
# - Grants are not specific to a schema. Once you're writer in a database, you
#   are writer to all schemas in it.
```

```
#
# The LDAP directory content is described in test/fixtures/openldap-data.ldif
#
# Adapt to your needs!
#
#
# File format version. Allows ldap2pg to check whether the file is supported.

      (cn=owners)
      (cn=readers)
      (cn=writers)
    )
    "
  role:
    name: '{member.cn}'
    options: LOGIN
    parent: "{cn}"
```

File Location

ldap2pg searches for configuration file in the following order:

1. ldap2pg.yml in current working directory.
2. ~/.config/ldap2pg.yml.
3. /etc/ldap2pg.yml.
4. /etc/ldap2pg/ldap2pg.yml.

If LDAP2PG_CONFIG or --config is set, ldap2pg skips searching the standard file locations. You can specify - to read configuration from standard input. This is helpful to feed ldap2pg with dynamic configuration.

File Structure

ldap2pg.yml is split in several sections:

- postgres: setup Postgres Pro> connection and inspection queries.
- ldap: configuration for LDAP client.
- privileges: the definition of privilege profiles.

- `rules`: the list of LDAP searches and associated mapping to roles and grants.

If you don't know how to begin, a simple tested and well commented [ldap2pg.yml](#) is a good starting point.

About YAML

YAML is a super-set of JSON. A JSON document is a valid YAML document. YAML is a very permissive format where indentation is meaningful. See [this YAML cheatsheet](#) for some example.

In `ldap2pg.yml` file, you will likely use wildcard for global pattern and curly brace for LDAP attribute injection. Take care of protecting these characters with quotes.

```
rules:
  - role: {cn} # It's an invalid YAML dict.
  - role: "{cn}" # It's a string with LDAP attribute injection
```

postgres Section

The `postgres` section defines custom SQL queries for Postgres Pro inspection.

The `postgres` section contains several `*_query` parameters. These parameters can be either a string containing an SQL query or a YAML list to return a static list of values, skipping execution of a query on Postgres Pro cluster.

`databases_query`

The SQL query to list databases names in the cluster. By default, `ldap2pg` searches databases it can connect to and it can reassign objects to its owner. `ldap2pg` loops databases to reassign objects before dropping a role. `ldap2pg` manages privilege on each database.

```
postgres:
  databases_query: "SELECT datname FROM pg_catalog.pg_databases;"
  # OR
  databases_query: [mydb]
```

Note

Configuring a `_query` parameter with a YAML list skips querying the cluster for inspection and forces `ldap2pg` to use a static value.

`fallback_owner`

Name of the role accepting ownership of database of dropped role.

Before dropping a role, `ldap2pg` reassigns objects and purges the access control list (ACL). `ldap2pg` starts by reassigning database owner by the targetted user. The new owner of the database is the *fallback owner*. Other objects are reassigned to each database owner.

`managed_roles_query`

The SQL query to list the name of managed roles.

`ldap2pg` restricts role deletion and privilege edition to managed roles. Usually, this query returns children of a dedicated group like `ldap_roles`. By default, `ldap2pg` manages all roles it has access to.

`public` is a special built-in role in Postgres Pro. If `managed_roles_query` returns `public` role in the list, `ldap2pg` will manage privileges on `public`. By default, `ldap2pg` manages `public` privileges.

The following example tells `ldap2pg` to manage `public` role, `ldap_roles` and any members of `ldap_roles`:

```
postgres:
  managed_roles_query: |
```

```
VALUES
  ('public'),
  ('ldap_roles')
UNION
SELECT DISTINCT role.rolname
FROM pg_roles AS role
JOIN pg_auth_members AS ms ON ms.member = role.oid
JOIN pg_roles AS parent
  ON parent.rolname = 'ldap_roles' AND parent.oid = ms.roleid
ORDER BY 1;
```

roles_blacklist_query

The SQL query returning name and global pattern to blacklist role from management. ldap2pg won't touch anything on these roles. Default value is [postgres, pg_*]. ldap2pg blacklists self user.

```
postgres:
  roles_blacklist_query:
  - postgres
  - "pg_*"
  - "rds_*
```

Warning

Beware that 'foo' is a YAML reference. You must quote pattern *beginning* with '*'.

schemas_query

The SQL query returning the name of managed schemas in a database. ldap2pg executes this query on each databases returned by `databases_query` only if ldap2pg manages privileges. ldap2pg loops on objects in theses schemas when inspecting GRANTS in the cluster.

```
postgres:
  schemas_query: |
    SELECT nspname FROM pg_catalog.pg_namespace
```

ldap Section

The `ldap` section customizes LDAP client behaviour. Configure connection using `ldap.conf` and `LDAP*` environment variables.

known_rdns

List of attributes known to be part of the distinguished name (DN).

ldap2pg skips sub-search for attributes in this list. e.g., {member.cn} won't trigger a sub-search on all members if `cn` is in `known_rdns`. Default value is [n, l, st, o, ou, c, street, dc, uid]. Add a value to fasten synchronization. Remove a value if an attribute is not part of the DN.

```
ldap:
  known_rdns: [cn, uid]
```

privileges Section

The `privileges` top-level section defines Postgres Pro privileges. It is a mapping defining privilege profiles, referenced later in synchronisation map's [grant rule](#). A privilege profile is a list of either references to a privilege type in a Postgres Pro ACL or other profiles. A privilege profile may include another profile, recursively. See [Managing Privileges](#) for details.

```
privileges:
  reading:
```

```
- on: GLOBAL DEFAULT
  type: SELECT
  object: TABLES
writing:
- reading
- on: GLOBAL
  type: SELECT
  object: TABLES
```

A privilege profile whose name starts with `_` is inactive unless included in an active profile.

object

Defines the target object for object-grained ACL.

Actually useful only for `GLOBAL DEFAULT` and `SCHEMA DEFAULT` ACL where the object is the target object class like `TABLES`, `SEQUENCES`, etc. [grant rule](#) defines target schema for `SCHEMA DEFAULT`.

```
privileges:
  reading:
  - type: SELECT
    on: GLOBAL DEFAULT
    object: TABLES
```

type

Type of privilege as described in [Section 5.7](#), e.g., `SELECT`, `REFERENCES`, `USAGE`, etc.

The value can be either a single string or a list of strings. Plural form `types` is valid. When multiple `types` are defined, a new privilege is defined for each type, each with the same attributes such as `on`.

```
privileges:
  reading:
  - type: USAGE
    on: SCHEMAS
```

on

Target ACL of privilege type. e.g., `TABLES`, `SEQUENCES`, `SCHEMAS`, etc. Note the special cases `ALL TABLES`, `ALL SEQUENCES`, etc. See [Managing Privileges](#) documentation for details.

```
privileges:
  reading:
  - type: SELECT
    on: ALL TABLES
```

rules **Section**

The top-level `rules` section defines synchronisation rules. The section contains is a YAML list. This is the only mandatory parameter in `ldap2pg.yaml`. Each item of `rules` is called a *mapping*. A mapping is a YAML dictionary with any of `role` or `grant` subsection. A mapping can optionnaly have a `description` field and a `ldapsearch` section.

```
rules:
- description: "Define DBA roles"
  ldapsearch:
    base: ...
  roles:
  - name: "{cn}"
    options: LOGIN SUPERUSER
```

The `ldapsearch` subsection is optional. You can define roles and grants without querying a directory.

description

A free string used for logging. This parameter does not accept mustache parameter injection.

ldapsearch

This directive defines LDAP search parameters. It is named after the `ldapsearch` command-line interface utility shipped by OpenLDAP project. Its behaviour should be mostly the same.

Note

This documentation refers to LDAP query as `search` while the word `query` is reserved for SQL query.

`ldapsearch` directives allow and require LDAP attributes injection in `role` and `grant` rules using curly braces. See [Querying Directory with LDAP](#) for details.

base, scope and filter

These parameters have the same meaning, definition and default as `base`, `scope` and `filter` arguments of `ldapsearch` command-line interface utility.

```
rules:
- ldapsearch:
    base: ou=people,dc=acme,dc=tld
    scope: sub
    filter: >
      (&f
        (member=*)
        (cn=group_*)
      )
```

joins

Customizes LDAP sub-search. The `joins` section is a dictionary with attribute name as key and LDAP search parameters as value. LDAP search parameters are the same as for top LDAP search. Actually, a single sub-search is supported.

```
rules:
- ldapsearch:
    joins:
      member:
        filter: ...
        scope: ...
    role:
      - name: "{member.sAMAccountName}"
```

The search base of sub-search is the value of the referencing attribute, e.g., each value of `member`. You can't customize the `base` attribute of sub-search. Likewise, `ldap2pg` infers attributes of sub-searches from `role` and `grant` rules. You can have only a single sub-search per top-level search. You can't do second-level sub-search.

See [Querying Directory with LDAP](#) for details.

Note

Executing a sub-search for each entry of a result set can be very heavy. You may optimize the query by using special LDAP search filter like `memberOf`. Refer to your LDAP directory administrator and documentation for details.

role

Defines a rule to describe one or more roles wanted in the target Postgres Pro cluster. This includes name, options, config, comment and membership. Plural form `roles` is valid. The value can be either a single role rule or a list of role rules.

```
rules:
- role:
  name: dba
  options: SUPERUSER LOGIN
- roles:
  - name: group0
    options: NOLOGIN
  - name: group1
    options: NOLOGIN
```

comment

Defines the SQL comment of a role. Default value is `Managed by ldap2pg`. Accepts LDAP attribute injection.

In case of LDAP attributes injection, you must take care of how many combinations will be generated. If the template generates a single comment, `ldap2pg` will copy the comment for each role generated by the [role rule](#). If the template generates multiple comments, `ldap2pg` associates name and comment. If there is more or less comments generated than name generated, `ldap2pg` fails.

The following example defines a static comment shared by all generated roles:

```
rules:
- roles:
  names:
  - alice
  - bob
  comment: "Static roles from YAML."
```

The following example generates a single comment from LDAP entry distinguished name, copied for all generated roles:

```
rules:
- ldapsearch:
  ...
  role:
    name: "{cn}"
    comment: "Generated from LDAP entry {dn}."
```

The following example generate a unique comment for each roles generated:

```
rules:
- ldapsearch:
  ...
  role:
    name: "{member.cn}"
    comment: "Generated from LDAP entry {member}."
```

Tip

If a role is defined multiple times, parents are merged. Other fields are kept as declared by the first definition of the role.

name

Name of the role wanted in the cluster. The value can be either a single string or a list of strings. Plural form `names` is valid. You can inject LDAP attributes in name using curly braces. When multiple names are defined, a new role is defined for each name, each with the same attributes such as `options` and `parents`. `comment` parameter has a special handling, see [comment](#).

```
rules:
- roles:
  name: "my-role-name"
```

When injecting LDAP attribute in name, each value of the LDAP attribute of each LDAP entry will define a new role. When multiple LDAP attributes are defined in the format, all combination of attributes are generated.

`ldap2pg` protects role name with double quotes in the target Postgres Pro cluster. Capitalization is preserved, spaces are allowed (even if it's a really bad idea).

`ldap2pg` applies [roles_blacklist_query](#) on this parameter.

options

Defines Postgres Pro role options. Can be an SQL-like string or a YAML dictionary. Valid options are `BYPASSRLS`, `CONNECTION LIMIT`, `LOGIN`, `CREATEDB`, `CREATEROLE`, `INHERIT`, `REPLICATION` and `SUPERUSER`. Available options vary following the version of the target Postgres Pro cluster and the privilege of `ldap2pg` user.

```
- roles:
- name: my-dba
  options: LOGIN SUPERUSER
- name: my-group
  options:
    LOGIN: no
    INHERIT: yes
```

config

Defines Postgres Pro configuration parameters that will be set for the role. Must be a YAML dictionary. Available configuration parameters vary following the version of the target Postgres Pro cluster. Some parameters require superuser privileges to be set. `ldap2pg` will fail if it does not have privilege to set a config parameter.

```
- roles:
- name: my-db-writer
  config:
    log_statement: mod
    log_min_duration_sample: 100
```

Setting `config` to `null` (the default) will disable the feature for the role. If `config` is a dict, `ldap2pg` will drop parameter set in cluster but not defined in `ldap2pg` YAML. To reset all parameters, set `config` to an empty dict like below.

```
- roles:
- name: reset-my-configuration
  config: {}
```

Note that LDAP attributes are not expanded in config values.

parent

Name of a parent role. A list of names is accepted. The plural form `parents` is valid too. Parent role is granted with `GRANT ROLE parent TO role;`. `parent` parameter accepts LDAP attributes

injection using curly braces. ldap2pg applies [roles_blacklist_query](#) on this parameter. Parent reference can be local roles not managed by ldap2pg.

```
rules:
- role:
    name: myrole
    parent: myparent
```

before_create

SQL snippet to execute before role creation. `before_create` accepts LDAP attributes injection using curly braces. You are responsible for escaping attribute with either `.identifier()` or `.string()`.

```
rules:
- ldapsearch: ...
  role:
    name: "{cn}"
    before_create: "INSERT INTO log VALUES ({cn.string()})"
```

after_create

SQL snippet to execute after role creation. `after_create` accepts LDAP attributes injection using curly braces. You are responsible for escaping attribute with either `.identifier()` or `.string()`.

```
rules:
- ldapsearch: ...
  role:
    name: "{sAMAccountName}"
    after_create: "CREATE SCHEMA {sAMAccountName.identifier()} AUTHORIZATION
{sAMAccountName.identifier()}"
```

grant

Defines a grant of a privilege to a role with corresponding parameters. Can be a mapping or a list of mapping. Plural form `grants` is valid too.

```
rules:
- grant:
    privilege: reader
    databases: __all__
    schema: public
    role: myrole
```

database

Scope the grant to one or more databases. May be a list of names. Plural form `databases` is valid. Special value `__all__` expands to all managed databases as returned by [databases_query](#). Defaults to `__all__`. Grants found in other databases will be revoked. Accepts LDAP attributes injection using curly braces.

This parameter is ignored for instance-wide privileges (e.g., on `LANGUAGE`).

privilege

Name of a privilege, within the privileges defined in [privileges](#) YAML section. May be a list of names. Plural form `privileges` is valid. Required, there is not default value. Accepts LDAP attribute injection using curly braces.

role

Name of the target role of the grant (*granted role* or *grantee*). Must be listed by [managed_roles_query](#). May be a list of names. Plural form `roles` is valid. Accepts LDAP attribute injection using curly braces. ldap2pg applies [roles_blacklist_query](#) on this parameter.

schema

Name of a schema within the schemas returned by `schemas_query`. Special value `__all__` means *all managed schemas in the databases*. May be a list of names. Plural form `schemas` is valid. Accepts LDAP attribute injection using curly braces.

This parameter is ignored for privileges on `DATABASE` and other instance-wide or database-wide privileges.

owner

Name of role to configure default privileges for. Special value `__auto__` fallbacks to managed roles having `CREATE` privilege on the target schema. May be a list of names. Plural form `owners` is valid. Accepts LDAP attribute injection using curly braces.

acls **Section**

Defines Postgres Pro ACLs. An ACL is set of queries to list GRANTS in the cluster and to manage them by granting or revoking item in the list. ACL is scoped to instance or database. References ACL in privileges profiles. Writing [a custom ACL](#) is tricky, ensure you understand both PostgreSQL and ldap2pg before.

acls

The `acls` top level section is a mapping defining ACLs. All fields are mandatory.

acls:

```
PROCEDURE:
  scope: database
  inspect: |
    WITH ...
  grant: GRANT ...
  revoke: REVOKE ...
```

scope

Scope of the ACL. Can be `instance` or `database`.

inspect

SQL query to list GRANTS in the cluster. The signature of the query depends on the scope. See [custom ACLs](#) for details.

grant

SQL query to grant a privilege. The query accepts templating using angle brackets. Some parameters are injected as keyword, i.e., as raw SQL. Other parameters are quoted as identifiers.

Available parameters:

- `<acl>` name of the ACL. Raw SQL.
- `<database>` name of database to grant on. Quoted identifier.
- `<grantee>` name of role to grant on. Quoted identifier.
- `<object>` name of object to grant on. Quoted identifier.
- `<owner>` name of role to grant to. Quoted identifier.
- `<privilege>` type of privilege. Raw SQL.
- `<schema>` name of schema to grant on. Quoted identifier.

revoke

SQL query to revoke a privilege. Like `grant`, the query accepts templating using angle brackets. Accepts same parameters as `grant`. Having different parameter between `GRANT` and `REVOKE` leads to unexpected behaviour.

Inspecting Postgres Pro Cluster

ldap2pg follows the explicit create/implicit drop and explicit grant/implicit revoke pattern. Thus properly inspecting cluster for what you want to drop/revoke is very crucial to succeed in synchronization.

ldap2pg inspects databases, schemas, roles, owners and grants with SQL queries. You can customize all these queries in the `postgres` YAML section with parameters ending with `_query`. See [the section called “postgres Section”](#) for details.

What Databases to Synchronize?

`databases_query` returns the flat list of databases to manage. The `databases_query` must return the default database as defined in `PGDATABASE`. When dropping roles, ldap2pg loops the databases list to reassign objects and clean GRANTS of the role to be dropped. This databases list also narrows the scope of GRANTS inspection. ldap2pg will revoke GRANTS only on these databases. See [the section called “postgres Section”](#) for details.

```
postgres:
  databases_query: |
    SELECT datname
    FROM pg_catalog.pg_database
    WHERE datallowconn IS TRUE;
```

Synchronize a Subset of Roles

By default, ldap2pg manages all roles from Postgres Pro, it has powers on, minus the default blacklist. If you want ldap2pg to synchronize only a subset of roles, you need to customize inspection query in [postgres:managed_roles_query](#). The following query excludes superusers from synchronization.

```
postgres:
  managed_roles_query: |
    SELECT 'public'
    UNION
    SELECT rolname
    FROM pg_catalog.pg_roles
    WHERE rolsuper IS FALSE
    ORDER BY 1;
```

ldap2pg will only drop, revoke, grant on roles returned by this query.

A common case for this query is to return only members of a group like `ldap_roles`. This way, ldap2pg is scoped to a subset of roles in the cluster.

The `public` role does not exist in the system catalog. Thus if you want ldap2pg to manage `public` privileges, you must include explicitly `public` in the set of managed roles. This is the default. Of course, even if `public` is managed, ldap2pg won't drop or alter it if it's not in the directory.

A safety net to completely ignore some roles is [roles_blacklist_query](#).

```
postgres:
  roles_blacklist_query: [postgres, pg_*] # This is the default.
```

Note

A pattern starting with a `'*'` *must* be quoted. Else you'll end up with a YAML error like “found undefined alias”.

Inspecting Schemas

For schema-wide privileges, ldap2pg needs to know managed schemas for each database. This is the purpose of `schemas_query`.

Configuring Owners Default Privileges

To configure default privileges, use the `default` keyword when referencing a privilege:

```
privileges:
  reading:
    - default: global
      type: SELECT
      on: TABLES
```

Then grant it using `grant` rule:

```
rules:
- grant:
  - privilege: reading
    role: readers
    schema: public
    owner: ownerrole
```

You can use `__auto__` as owner. For each schema, `ldap2pg` will configure every managed role having `CREATE` privilege on schema.

```
rules:
- grant:
  - privilege: reading
    role: readers
    schema: public
    owner __auto__
```

`ldap2pg` configures default privileges last, after all effective privileges. Thus `CREATE` on schema is granted before `ldap2pg` inspects creators on schemas.

Static Queries

You can replace all queries with a **static list** in YAML. This list will be used as if returned by Postgres Pro. That's very handy to freeze a value like databases or schemas.

```
postgres:
  databases_query: [postgres]
  schemas_query: [public]
```

Managing Roles

`ldap2pg` synchronizes Postgres Pro roles in three steps:

1. Loop `rules` and generate wanted roles list from `role` rules.
2. Inspect Postgres Pro for existing roles, their options and their membership.
3. Compare the two roles sets and apply to the Postgres Pro cluster using `CREATE`, `DROP` and `ALTER`.

Each `role` entry in `rules` is a rule to generate zero or more roles with the corresponding parameters. A `role` rule is like a template. `role` rules allow you to deduplicate membership and options by setting a list of names.

You can mix static rules and dynamic rules in the same file.

Running Unprivileged

`ldap2pg` is designed to run unprivileged. Synchronization user needs `CREATEROLE` option to manage other unprivileged roles. `CREATEDB` options allow synchronization user to manage database owners.

`ldap2pg` user must have `createrole_self_grant` set to `inherit`, set to properly handle groups.

```
CREATE ROLE ldap2pg LOGIN CREATEDB CREATEROLE;
ALTER ROLE ldap2pg SET createrole_self_grant TO 'inherit,set';
```

Running unprivileged before PostgreSQL 16 is actually flawed. You'd better just run `ldap2pg` with superuser privileges, you won't feel falsely secured.

Ignoring Roles

`ldap2pg` totally ignores roles matching one of the global pattern defined in `roles_blacklist_query`:

```
postgres:
  # This is the default value.
  roles_blacklist_query: [postgres, pg_*]
```

The role blacklist is also applied to grants. `ldap2pg` will never apply `grant` or `revoke` on a role matching one of the blacklist patterns.

`ldap2pg` blacklists its running user.

Membership

`ldap2pg` manages parents of roles. `ldap2pg` applies `roles_blacklist_query` to parents. However, `ldap2pg` grants unmanaged parents. This way, you can create a group manually and manage its members using `ldap2pg`.

Querying Directory with LDAP

`ldap2pg` reads LDAP searches in `rules` steps in the `ldapssearch` entry.

A LDAP search is **not** mandatory. `ldap2pg` can create roles defined statically from YAML. Each LDAP search is executed once and only once. There is neither loop nor deduplication of LDAP searches.

Tip

`ldap2pg` logs LDAP searches as `ldapssearch` commands. Enable verbose messages to see them.

You can debug a failing search by copy-pasting the command in your shell and update parameters. Once you are okay, translate back the right parameters in the YAML.

Configuring Directory Access

`ldap2pg` reads directory configuration from `ldaprc` file and `LDAP*` environment variables. Known LDAP options are:

- BASE
- BINDDN
- PASSWORD
- REFERRALS
- SASL_AUTHCID
- SASL_AUTHZID
- SASL_MECH
- TIMEOUT
- TLS_REQCERT
- NETWORK_TIMEOUT
- URI

See `ldap.conf(5)` man page for the meaning and format of each options.

Injecting LDAP Attributes

Several parameters accept LDAP attribute injection using curly braces. To do this, wrap attribute name with curly braces like `{cn}` or `{sAMAccountName}`. `ldap2pg` expands to each value of the attribute for each entries of the search.

If the parameter has multiple LDAP attributes, `ldap2pg` expands to all combinations of attributes for each entries.

Given the following LDAP entries:

```
dn: uid=dimitri,cn=Users,dc=bridoulou,dc=fr
objectClass: inetOrgPerson
uid: dimitri
sn: Dimitri
cn: dimitri
mail: dimitri@bridoulou.fr
company: external
dn: cn=domitille,cn=Users,dc=bridoulou,dc=fr
objectClass: inetOrgPerson
objectClass: organizationalPerson
objectClass: person
objectClass: top
cn: domitille
sn: Domitille
company: acme
company: external
```

The format `{company}_{cn}` with the above LDAP entries generates the following strings:

- `acme_domitille`
- `external_domitille`
- `external_dimitri`

The pseudo attribute `dn` is always available and references the distinguished name (DN) of the original LDAP entry.

Accessing RDN and Sub-Search

If an attribute type is DN, you can refer to a relative distinguished name (RDN) with a dot, like this: `<attribute>.<rdn>`. If an RDN has multiple values, only the first value is returned. There is no way to access other values.

For example, if a LDAP entry has `member` attribute with value `cn=toto,cn=Users,dc=bridoulou,dc=fr`, the `{member.cn}` format will generate `toto`. The `{member.dc}` format will generate `ldap`. There is no way to access `acme` and `fr`.

Known RDN are `cn`, `l`, `st`, `o`, `ou`, `c`, `street`, `dc`, and `uid`. Other attributes trigger a sub-search. The format `{member.sAMAccountName}` will issue a sub-search for all `member` value as LDAP search base narrowed to `sAMAccountName` attribute.

LDAP Attribute Case

When injecting a LDAP attribute with curly braces, you can control the case of the value using `.lower()` or `.upper()` methods.

```
- ldapsearch: ...
  role: "{cn.lower()}"
```

Managing Privileges

Managing privileges is tricky. `ldap2pg` tries to make this simpler and safer.

Basics

The base design of `ldap2pg` is as follows. Instead of revoke-everything-regrant design, `ldap2pg` uses inspect-modify design. The process is the same as for roles synchronization, including the three following steps:

1. Loop `rules` and generate wanted grants set.

2. Inspect Postgres Pro cluster for granted privileges.
3. Compare the two sets of grants and update the Postgres Pro cluster using `grant`, `revoke`.

ldap2pg represents privileges with these core objects:

- **Privilege:** An action on an object. e.g., `CONNECT ON DATABASE`.
- **grant:** a privilege granted to a role on an object.
- **ACL:** a list of grants.
- **profile:** a list of privileges.
- **rule:** a template to generate wanted grants.

`ldap2pg.yml` holds profiles and grant rule. ldap2pg synchronizes ACL one at a time, database by database. ldap2pg synchronizes default privileges last.

By default, ldap2pg does not manage any privileges. To enable privilege management, you must define at least one active profile in `privileges` section. The simplest way is to reuse [built-in privilege profiles](#) shipped with ldap2pg in an active custom profile.

Defining a Privilege Profile

A privilege profile is a list of references to either a privilege type on an ACL or another profile. ldap2pg ships several predefined ACL like `DATABASE`, `LANGUAGE`, etc. A privilege type is `USAGE`, `CONNECT` and so on, as described in [Section 5.7](#). See `privileges` YAML section documentation for details on privilege profile format.

ldap2pg loads referenced ACL by inspecting Postgres Pro cluster with carefully crafted queries. ldap2pg inspects only ACL referenced in at least one profile. Inspected grants are supposed to revocation unless explicitly wanted by a `grant` rule.

Warning

If it's not granted, revoke it!

Once an ACL is inspected, ldap2pg *revokes* all grants found in Postgres Pro instance and not required by a `grant` rule in `rules`.

Extended Intance Inspection

When managing privileges, ldap2pg has deeper inspection of Postgres Pro instance. ldap2pg inspects schemas after roles synchronization and before synchronizing privileges. ldap2pg inspects objects owner after privileges synchronization and before synchronizing default privileges. An object owner is a role having `CREATE` privilege on the schema.

Granting Privilege Profile

Inspecting millions of privileges may consume a lot of resources on Postgres Pro instance. Revoking privileges is known to be slow in Postgres Pro. The best practice is to grant privileges to a group role and let user inherit privileges. With ldap2pg, you can define static groups in YAML and inherit them when creating roles from directory.

Use `grant rule` to grant a privilege profile to one or more roles. When granting privileges, you must define the grantee. You may scope the grant to one or more databases, one or more schemas. If the privilege profile includes default privileges, you may define the owners on which to configure default privileges.

By default, a grant applies to all managed databases as returned by `databases_query`, to all schemas of each database as returned by `schemas_query`.

Example

The following example defines three privileges profile. The `rules` defines three groups and grant the corresponding privilege profile:

```
privileges:
  reading:
    - __connect__
    - __usage_on_schemas__
    - __select_on_tables__
  writing:
    - reading # include reading privileges
    - __insert_on_tables__
    - __update_on_tables__
  owning:
    - writing
    - __create_on_schemas__
    - __truncate_on_tables__
rules:
- role:
  - names:
    - readers
    - writers
    - owners
    options: NOLOGIN
- grant:
  - privilege: reading
    role: readers
  - privilege: writing
    role: writers
  - privilege: owning
    role: owners
```

Another way of including reading profile in writing is to writers group to inherit readers group.

Managing Public Privileges

Postgres Pro has a pseudo-role called `public`. It's a wildcard role meaning *every users*. All roles in Postgres Pro implicitly inherits from this `public` role. Granting a privilege to `public` role grants to every roles now and in the future.

Postgres Pro also has the `public` schema. The `public` schema is a real schema available in all databases.

Postgres Pro has some built-in privileges for `public` role. Especially for the `public` schema. For example, `public` has `CONNECT` on all databases by default. This means that you only rely on `pg_hba.conf` to configure access to databases, which requires administrative access to the cluster and a `pg_reload_conf()` call.

By default, `ldap2pg` includes `public` role in managed roles. Predefined ACL knows how to inspect built-in privileges granted to `public`. If you want to preserve `public` role, rewrite `managed_roles_query` to not include `public`.

Managing Default Privileges

If you grant `SELECT` privileges on all tables in a schema to a role, this won't apply to new tables created afterward. Instead of reexecuting `ldap2pg` after the creation of every objects, Postgres Pro provides a way to define default privileges for future objects.

Postgres Pro attaches default privileges to the creator role. When the role creates an object, Postgres Pro applies the corresponding default privileges to the new object. e.g., `ALTER DEFAULT PRIVILEGES FOR ROLE bob GRANT SELECT ON TABLES TO alice;` ensures every new table bob creates will be selectable by alice:

If `ldap2pg` creates and drops creator roles, you want `ldap2pg` to properly configure default privileges on these roles. If you wonder whether to manage privileges with `ldap2pg`, you should at least manage default privileges along creator.

ldap2pg inspects the creators from Postgres Pro, per schemas, not LDAP directory. A creator is a role with `LOGIN` option and `CREATE` privilege on a schema. You can manually set the target owner of a grant to any managed roles.

ldap2pg does not configure privileges on `__all__` schemas. You are supposed to use `GLOBAL DEFAULT ACL` instead. If you want to grant/revoke default privilege per schema, you must reference `SCHEMA DEFAULT ACL`.

The following example configures default privileges for alice to allow bob to `SELECT` on future tables created by alice.

```
privileges:
  reading:
    - type: SELECT
      on: SCHEMA DEFAULT
      object: TABLES
  owning:
    - type: CREATE
      on: SCHEMAS

rules:
- roles:
    names:
      - alice
      - bob
    options: LOGIN
- grant:
    privilege: owning
    role: alice
- grant:
    privilege: reading
    role: bob
```

Postgres Pro has hard-wired global default privileges. If a role does not have global default privileges configured, Postgres Pro assumes some defaults. By default, Postgres Pro just grants privileges on owner. You can see them once you modify the default privileges. Postgres Pro will copy the hard-wired values along with your granted privileges.

If you don't explicitly re-grant these privileges in `ldap2pg.yml`, ldap2pg will revoke these hard-wired privileges. Actually, an owner of table don't need to be granted `SELECT` on its own tables. Thus, the hard-wired defaults are useless. You can let ldap2pg purge these useless defaults.

Built-in Privileges

ldap2pg provides some built-in ACLs and predefined privilege profiles for recurrent usage. There is **no warranty** on these privileges. You have to check privileges configuration on your databases just like you should do with your own code.

Using Predefined Privilege Profiles

A privilege profile is a list of references to a privilege type in an ACL. In ldap2pg, an ACL is a set of queries to inspect, grant revoke privilege on a class of objects. The inspect query expands `aclitem` Postgres Pro type to list all grants from system catalog. Privilege profile can include another profile.

Built-in privilege profile starts and ends with `__`. ldap2pg [disables privilege profile](#) starting with `_`. Thus you have to include built-in privileges profile in another profile to enable them. If two profiles reference the same privilege, ldap2pg will inspect it once.

```
privileges:
  ro:
    - __connect__
```

```
- __usage_on_schemas__
- __select_on_tables__

rw:
- ro
- __insert__

ddl:
- rw
- __all_on_schemas__

rules:
- grant:
    privilege: ddl
    database: mydb
    role: admins
```

Built-in profile's name follows the loose convention below:

- `..._on_all_tables__` references `ALL TABLES IN SCHEMA ACL`. Likewise for sequences and functions.
- `__default_...__` references both global and schema-wide default privileges.
- `..._on_tables__` groups `..._on_all_tables__` and `__default_..._on_tables__`.
- Group starting with `__all_on_...__` is *equivalent* to `ALL PRIVILEGES` in SQL. However, each privilege will be granted individually.
- A privilege specific to one object type does not have `_on_<type>` suffix. E.g., `__delete_on_tables__` is an alias of `__delete__`.

This page does not document the SQL standard and the meaning of each SQL privileges. You will find information on SQL privileges in [GRANT documentation](#) and [ALTER DEFAULT PRIVILEGES documentation](#).

ACL Reference

Here is the list of built-in ACLs.

For effective privileges:

DATABASE

Privilege on database like `CONNECT`, `CREATE`, etc.

SCHEMA

Manage `USAGE` and `CREATE` on schema.

LANGUAGE

Manage `USAGE` on procedural languages.

ALL FUNCTIONS IN SCHEMA

Manage `EXECUTE` on all functions per schema.

ALL SEQUENCES IN SCHEMA

Like above but for sequences.

ALL TABLES IN SCHEMA

Like above but for tables and views.

GLOBAL DEFAULT

Manage default privileges on database.

SCHEMA DEFAULT

Manage default privileges per schema.

`ALL ... IN SCHEMA` ACL inspects whether a privilege is granted to only a subset of objects. This is a *partial* grant. A partial grant is either revoked if unwanted or re-granted if expected.

You can reference these ACLs using [privileges: on](#) parameter in YAML. Like this:

```
privileges:
  myprofile:
    - type: SELECT
      on: ALL TABLES IN SCHEMA
```

Default privileges reference a privilege type and a class of objects. `ldap2pg` inspects default privileges for the following object classes:

- SEQUENCES
- FUNCTIONS
- TABLES

You must reference object class in privilege profile using [object](#) parameter in YAML.

You cannot configure custom ACL (yet).

Profiles Reference

Profile `__all_on_functions__`
[__execute_on_functions__](#)

Profile `__all_on_schemas__`

- [__create_on_schemas__](#)
- [__usage_on_schemas__](#)

Profile `__all_on_sequences__`

- [__select_on_sequences__](#)
- [__update_on_sequences__](#)
- [__usage_on_sequences__](#)

Profile `__all_on_tables__`

- [__delete_on_tables__](#)
- [__insert_on_tables__](#)
- [__select_on_tables__](#)
- [__truncate_on_tables__](#)
- [__update_on_tables__](#)
- [__references_on_tables__](#)
- [__trigger_on_tables__](#)

Profile `__delete_on_tables__`

- [__default_delete_on_tables__](#)
- [__delete_on_all_tables__](#)

Profile `__execute_on_functions__`

- [__default_execute_on_functions__](#)
- [__execute_on_all_functions__](#)

Profile `__insert_on_tables__`

- [__default_insert_on_tables__](#)
- [__insert_on_all_tables__](#)

Profile `__references_on_tables__`

- `__default_references_on_tables__`
- `__references_on_all_tables__`

Profile `__select_on_sequences__`

- `__default_select_on_sequences__`
- `__select_on_all_sequences__`

Profile `__select_on_tables__`

- `__default_select_on_tables__`
- `__select_on_all_tables__`

Profile `__trigger_on_tables__`

- `__default_trigger_on_tables__`
- `__trigger_on_all_tables__`

Profile `__truncate_on_tables__`

- `__default_truncate_on_tables__`
- `__truncate_on_all_tables__`

Profile `__update_on_sequences__`

- `__default_update_on_sequences__`
- `__update_on_all_sequences__`

Profile `__update_on_tables__`

- `__default_update_on_tables__`
- `__update_on_all_tables__`

Profile `__usage_on_sequences__`

- `__default_usage_on_sequences__`
- `__usage_on_all_sequences__`

Privileges Reference

Here is the list of predefined privileges:

Name	Manages
<code>__connect__</code>	CONNECT ON DATABASE
<code>__create_on_schemas__</code>	CREATE ON SCHEMA
<code>__delete_on_all_tables__</code>	DELETE ON ALL TABLES IN SCHEMA
<code>__execute_on_all_functions__</code>	EXECUTE ON ALL FUNCTIONS IN SCHEMA
<code>—</code>	
<code>__insert_on_all_tables__</code>	INSERT ON ALL TABLES IN SCHEMA
<code>__references_on_all_tables__</code>	REFERENCES ON ALL TABLES IN SCHEMA
<code>—</code>	
<code>__select_on_all_sequences__</code>	SELECT ON ALL SEQUENCES IN SCHEMA
<code>__select_on_all_tables__</code>	SELECT ON ALL TABLES IN SCHEMA
	TEMPORARY ON DATABASE
<code>__trigger_on_all_tables__</code>	TRIGGER ON ALL TABLES IN SCHEMA
<code>__truncate_on_all_tables__</code>	TRUNCATE ON ALL TABLES IN SCHEMA
<code>__update_on_all_sequences__</code>	UPDATE ON ALL SEQUENCES IN SCHEMA
<code>__update_on_all_tables__</code>	UPDATE ON ALL TABLES IN SCHEMA

Name	Manages
__usage_on_all_sequences__	USAGE ON ALL SEQUENCES IN SCHEMA
__usage_on_schemas__	USAGE ON SCHEMA

Default Privileges Reference

Here is the list of predefined default privileges. Default privilege profile references both global and schema defaults.

Name	Manages
__default_delete_on_tables__	DELETE ON TABLES
__default_execute_on_functions__	EXECUTE ON FUNCTIONS
__default_insert_on_tables__	INSERT ON TABLES
__default_references_on_tables__	REFERENCES ON TABLES
__default_select_on_sequences__	SELECT ON SEQUENCES
__default_select_on_tables__	SELECT ON TABLES
__default_trigger_on_tables__	TRIGGER ON TABLES
__default_truncate_on_tables__	TRUNCATE ON TABLES
__default_update_on_sequences__	UPDATE ON SEQUENCES
__default_update_on_tables__	UPDATE ON TABLES
__default_usage_on_sequences__	USAGE ON SEQUENCES

Usage Recipes

In this section, you'll find some recipes for various use cases of `ldap2pg`.

Configure `pg_hba.conf` with LDAP

`ldap2pg` does **NOT** configure Postgres Pro for you. You should carefully read [Section 19.10](#) for this point. Having Postgres Pro properly configured **before** writing `ldap2pg.yaml` is a good start. Here is the steps to setup Postgres Pro with LDAP in the best order:

1. Write the LDAP search and test it with `ldapsearch(1)`. This way, you can also check how you connect to your LDAP directory.
2. In Postgres Pro cluster, **manually** create a single role having its password in LDAP directory.
3. Edit `pg_hba.conf` following [Section 19.10](#) until you can effectively login with the single role and the password from LDAP.

Once you have LDAP authentication configured in Postgres Pro cluster, you can move to automate role creation from the LDAP directory using `ldap2pg`:

1. Write a simple `ldap2pg.yaml` with only one LDAP search just to setup `ldap2pg` connection parameters for Postgres Pro and LDAP connection. `ldap2pg` always runs in dry mode by default, so you can safely loop `ldap2pg` execution until you get it right.

2. Then, complete `ldap2pg.yaml` to fit your needs following [the section called “Command-Line Reference”](#). Run `ldap2pg` for real and check that `ldap2pg` maintain your single test role, and that you can still connect to the cluster with it.
3. Finally, you must decide when and how you want to trigger synchronization: a regular cron tab/an Ansible task/manually/ other. Ensure `ldap2pg` execution is frequent, on purpose and notified.

Search LDAP Directory

The first step is to search your LDAP server with `ldapsearch(1)`, the command-line interface tool from OpenLDAP. Like this:

```
$ ldapsearch -H ldaps://ldap.ldap2pg.docker -U testsasl -W
Enter LDAP Password:
SASL/DIGEST-MD5 authentication started
SASL username: testsasl
SASL SSF: 128
SASL data security layer installed.
# extended LDIF
#
# LDAPv3
...
# search result
search: 4
result: 0 Success

# numResponses: 16
# numEntries: 15
$
```

Now save the settings in `ldaprc`:

```
LDAPURI ldaps://ldap.ldap2pg.docker
LDAPSASL_AUTHCID testsasl
```

And in environment: `LDAPPASSWORD=secret`

Next, update your `ldapsearch` to properly match role entries in LDAP server:

```
$ ldapsearch -H ldaps://ldap.ldap2pg.docker -U testsasl -W -b
cn=dba,ou=groups,dc=ldap,dc=ldap2pg,dc=docker ' ' member
...
# dba, groups, ldap.ldap2pg.docker
dn: cn=dba,ou=groups,dc=ldap,dc=ldap2pg,dc=docker
member: cn=Alan,ou=people,dc=ldap,dc=ldap2pg,dc=docker
member: cn=albert,ou=people,dc=ldap,dc=ldap2pg,dc=docker
member: cn=ALICE,ou=people,dc=ldap,dc=ldap2pg,dc=docker

# search result
search: 4
result: 0 Success

...
$
```

Now translate the query in `ldap2pg.yaml` and associate a role mapping to produce roles from each values of each entries returned by the LDAP search:

```
- ldapsearch:
  base: cn=dba,ou=groups,dc=ldap,dc=ldap2pg,dc=docker
  role:
    name: '{member.cn}'
```

```
options: LOGIN SUPERUSER
```

Test it:

```
$ ldap2pg
...
Querying LDAP cn=dba,ou=groups,dc=ldap,dc=ldap2pg,dc=docker...
Would create alan.
Would create albert.
Would update options of alice.
...
Comparison complete.
$
```

Read further on how to control role creation from LDAP entry in [Configuration](#). Once you're satisfied with the comparison output, go real with `--real`.

Using LDAP High-Availability

ldap2pg supports LDAP high availability out of the box just like any OpenLDAP client. Use a space-separated list of URIs to tell all servers.

```
$ LDAPURI="ldaps://ldap1 ldaps://ldap2" ldap2pg
```

See `ldap.conf(5)` for further details.

Running as Non-Superuser

Since Postgres Pro> provides a `CREATEROLE` role option, you can manage roles without superuser privileges. Security-wise, it's a good idea to manage roles without superuser privileges.

Warning

Up to Postgres Pro 15, having `CREATEROLE` is roughly equivalent to being superuser. This because `CREATEROLE` user can grant themselves almost every privileges. Thus ldap2pg supports running unprivileged against Postgres Pro 16 and later only.

ldap2pg supports this case. However, you must be careful about the limitations. Let's call the non-superuser role creating other roles `creator`.

- You can't manage some roles options like `SUPERUSER`, `BYPASSRLS` and `REPLICATION`. Thus you won't be able to detect spurious superusers.
- Ensure `creator` can revoke all grants of managed users.

Removing All Roles

If ever you want to clean all roles in a Postgres Pro cluster, ldap2pg could be helpful. You must explicitly define empty rules.

```
$ echo '{version: 6, rules: []}' | ldap2pg --config -
...
Empty synchronization map. All roles will be dropped!
...
```

In this example, default blacklist applies. ldap2pg never drops its connection role.

ldap2pg as Docker Container

We assume that you are already familiar with Docker and willing to save the setup time.

To run the container simply use the command:

```
$ docker run --rm dalibo/ldap2pg --help
```

The Docker image of `ldap2pg` uses the same configuration options as explained in the [Command-Line Interface](#) and [ldap2pg.yml](#) sections. You can mount the `ldap2pg.yml` configuration file.

```
$ docker run --rm -v ${PWD}/ldap2pg.yml:/workspace/ldap2pg.yml dalibo/ldap2pg
```

You can also export some environment variables with the `-e` option:

```
$ docker run --rm -v ${PWD}/ldap2pg.yml:/workspace/ldap2pg.yml -e
PGDSN=postgres://postgres@localhost:5432/ -e LDAPURI=ldaps://localhost -e
LDAPBINDDN=cn=you,dc=entreprise,dc=fr -e LDAPPASSWORD=pasglop dalibo/ldap2pg
```

Make sure your container can resolve the hostname you are pointing to. If you use some internal name resolution, be sure to add the `-dns=` option to your command pointing to your internal DNS server. You can also find more information [here](#).

Custom ACL

`ldap2pg` comes with built-in ACLs for common objects like `DATABASE`, `SCHEMA`, `TABLE`, `FUNCTION`, etc. Postgres Pro has a lot of other objects like `FOREIGN DATA WRAPPER`, `FOREIGN SERVER`, `FOREIGN TABLE`, `TYPE`, etc. You may also want to manage custom ACL or something else. Writing a custom ACL should help you get the job done.

Note

Writing a custom ACL is quite advanced. You should be familiar with Postgres Pro ACLs and `ldap2pg` configuration. Ensure you have read [Managing Privileges](#) and [ldap2pg.yml File Reference](#) sections, have a good understanding of [Postgres Pro ACL documentation](#) and have successfully synchronized privileges with `ldap2pg`.

Define custom ACL in YAML configuration file.

Use Case

Say you have a custom `enum` type `myenum` in your database.

```
CREATE TYPE public.myenum AS ENUM ('toto', 'titi', 'tata');
```

We want to manage privileges on this object, eventually other types, with a custom ACL.

Naming

Name your ACL after the keyword in `GRANT` or `REVOKE` statement. From `GRANT USAGE ON TYPE mytype TO myrole`, name your ACL `TYPE`.

```
acls:
  TYPE:
    ...
```

Scope

Postgres Pro defines user types per schema. Since we'll hardcode the schema, we will scope our ACL to database.

```
acls:
  TYPE:
    scope: database
```

Grant and Revoke

Writing `GRANT` and `REVOKE` statements is the easiest part. See [grant](#) for details on query format. We'll use the `object` field of `grant` to store the name of the type. Public schema is hardcoded, as explained above.

```
acls:
  TYPE:
```

```
scope: database
grant: GRANT <privilege> ON TYPE public.<object> TO <grantee>;
revoke: REVOKE <privilege> ON TYPE public.<object> FROM <grantee>;
```

Inspect

The inspect query is the most difficult part. You need to master `aclitem`, `aclexplode` and `acldefault` Postgres Pro system built-ins. The signature of the inspect query depends on the scope of the ACL.

For instance scope:

- `type`: a string describing privilege type as SQL keyword.
- `object`: a string describing object name as SQL identifier.
- `grantee`: a string describing role name as SQL identifier.

For database scope:

- `type`: a string describing privilege type as SQL keyword.
- `object`: a string describing object name as SQL identifier.
- `grantee`: a string describing role name as SQL identifier.
- `partial`: a boolean indicating if the grant is partial.

`partial` tells `ldap2pg` to re-grant ALL ... IN SCHEMA privileges. Since our ACL is handling one object at a time, `partial` will always be `false`.

`ldap2pg` sends a single parameter to inspect query: the effective list of privilege types managed by the configuration. This list is an array of text. `ldap2pg` expects query to filter other privileges out of the list.

For TYPE ACL, we will inspect privileges on `pg_type` system catalog.

```
acls:
  TYPE:
    scope: database
    grant: GRANT <privilege> ON <acl> public.<object> TO <grantee>;
    revoke: REVOKE <privilege> ON <acl> public.<object> FROM <grantee>;
    inspect: |
      WITH grants AS (
        SELECT typename,
               (aclexplode(COALESCE(typancl, acldefault('T', typowner)))).privilege_type
      AS priv,
               (aclexplode(COALESCE(typancl, acldefault('T',
typowner)))).grantee::regrole::text AS grantee
        FROM pg_catalog.pg_type
        WHERE typnamespace::regnamespace = 'public'::regnamespace
        AND typtype <> 'b' -- exclude base type.
      )
      SELECT grants.priv AS "privilege",
             grants.typname AS "object",
             CASE grants.grantee WHEN '-' THEN 'public' ELSE grants.grantee END AS
grantee,
             FALSE AS partial
      FROM grants
      WHERE "priv" = ANY ($1)
      ORDER BY 2, 3, 1
    ;
```

As you see, it's not an easy query. This query works on Postgres Pro 17.

Usage

You can now use your custom ACL in a profile. Reference object in profile, not in grant rule.

```
privileges:
```

```
custom:
- type: USAGE
  on: TYPE
  object: myenum

rules:
- roles:
  names:
  - alice
  grant:
  privilege: custom
  role: alice
```

You must reference all types manually in the profile. Executing `ldap2pg` should produce changes in your database:

```
$ ldap2pg
...
16:52:02 CHANGE Would Revoke privileges.          grant="USAGE ON TYPE
myenum TO public" database=db0
16:52:02 CHANGE Would Grant privileges.          grant="USAGE ON TYPE
myenum TO alice" database=db0
16:52:02 INFO    Comparison complete.            searches=0 roles=1
queries=5 grants=1
16:52:02 INFO    Use --real option to apply changes.
16:52:02 INFO    Done.                          elapsed=44.345229ms
mempeak=1.6MiB ldap=0s inspect=28.992071ms sync=0s
```

That's it.

Debugging

If you encounter problem, isolate the issue. Reduce the configuration to your custom ACL. Synchronize a single role, grant to it. Avoid LDAP searches, use only static rules. Synchronize a single database. Enable debug messages with `--verbose` option.

`ldap2pg` works database per database then ACL per ACL. The messages for each ACL are as follow:

First line about your ACL has `acl=TYPE` record attribute.

```
17:13:35 DEBUG   Inspecting grants.                acl=TYPE
scope=database database=db0
```

Then you have messages for inspection: query and arguments. For each grant returned, a `Found grant.` message appears.

```
17:13:35 DEBUG   Executing SQL query:
WITH grants AS (
...
WHERE "priv" = ANY ($1)
ORDER BY 2, 3, 1
;
  arg=[USAGE]
17:13:35 DEBUG   Found grant in Postgres instance.  grant="USAGE ON TYPE
myenum TO public" database=db0
```

Then, `ldap2pg` expands grants generated by rule. For each grant generated, a `Wants grant.` message is printed.

```
17:13:35 DEBUG   Wants grant.                      grant="USAGE ON TYPE
myenum TO alice" database=db0
```

Finally, ldap2pg prints changes it would apply.

```
17:13:35 CHANGE Would Revoke privileges. grant="USAGE ON TYPE
myenum TO public" database=db0
17:13:35 DEBUG Would Execute SQL query:
REVOKE USAGE ON TYPE public."myenum" FROM "public";
17:13:35 CHANGE Would Grant privileges. grant="USAGE ON TYPE
myenum TO alice" database=db0
17:13:35 DEBUG Would Execute SQL query:
GRANT USAGE ON TYPE public."myenum" TO "alice";
```

At the end, ldap2pg prints a conclusion message, even if no changes are required.

```
17:13:35 DEBUG Privileges synchronized. acl=TYPE database=db0
```

pgbadger

pgbadger — rapidly analyze Postgres Pro logs, producing detailed reports and graphs

Synopsis

```
pgbadger [connection-option...] [option...] [logfile...]
```

Description

pgbadger is a Postgres Pro/PostgreSQL log analyzer, which rapidly provides detailed reports based on your log files. pgbadger is provided with Postgres Pro as a standalone Perl script.

logfile can be a single log file, a list of files or a shell command that returns a list of files. To get log content from the standard input, pass “-” as *logfile*.

pgbadger can parse huge log files and compressed files. It can autodetect your log file format (syslog, stderr, csvlog or jsonlog) if the file is long enough. Supported compressed formats are gzip, bzip2, lz4, xz, zip and zstd. For the xz format, you must have an xz version higher than 5.05, which supports the `--robot` option. For pgbadger to determine the uncompressed file size for the lz4 format, the file must be compressed with the `--content-size` option.

pgbadger supports any format of log-line prefixes that can be specified through the [log_line_prefix](#) configuration setting of your `postgresql.conf` configuration file, provided that at least `%t` and `%p` are specified.

[pgbouncer](#) log files can also be parsed.

To speed up log parsing, you can use any of these multiprocessing modes: one core per log file and multiple cores per file. These modes can be combined.

pgbadger can also parse remote log files fetched using a passwordless SSH connection. This mode can be used with compressed files and even supports multiprocessing with multiple cores per file.

Examples of reports can be found at <https://pgbadger.darold.net/#reports>.

Limitations

pgbadger currently has the following limitations:

- Multiprocessing is not supported for compressed log files and CSV files, as well as on Windows.
- CSV format of log files cannot be parsed remotely.
- csvlog logs cannot be passed from the standard input.

Setup and Configuring

pgbadger is provided with Postgres Pro Standard as a separate pre-built package `pgbadger` (for the detailed installation instructions, see [Chapter 16](#)). Once you have pgbadger installed, complete the setup described in sections below.

[Optional] Set up Parsing Specific Log Formats

If you plan to parse CSV log files, install `Text::CSV_XS` Perl module.

[Optional] Set up Export of Statistics

If you want to export statistics as a JSON file, install `JSON::XS` Perl module:

To install this optional module:

- On a Debian-based system, run:

```
sudo apt-get install libjson-xs-perl
```

- On an RPM system, run:

```
sudo yum install perl-JSON-XS
```

[Optional] Set up Parsing Compressed Log Files

By default, pgbadger autodetects the compressed log file format from the file extension and uses decompression utilities accordingly:

- `zcat` for `gz`
- `bzcat` for `bz2`
- `lz4cat` for `lz4`
- `zstdcat` for `zst`
- `unzip` or `xz` for `zip` or `xz`

If the needed utility is outside of your `PATH` directories, use the `--zcat` command-line option to specify the path to the decompression utility. For example:

```
--zcat="/usr/local/bin/gunzip -c" or --zcat="/usr/local/bin/bzip2 -dc"  
--zcat="C:\tools\unzip -p"
```

Note

With the default autodetection of the compressed file format, you can mix `gz`, `bz2`, `lz4`, `xz`, `zip` and `zstd` log files. Once you specified a custom value of `--zcat`, mixing compressed files of different formats is longer possible.

Configure Your Postgres Pro Server

Set the values of certain configuration parameters in your `postgresql.conf`:

- Set up logging SQL queries.

To enable SQL query logging and have the query statistics include actual query strings, set

```
log_min_duration_statement = 0
```

On a busy server you may want to increase this value to only log queries with a longer duration.

If you just want to report the duration and number of queries and do not want details of queries, set `log_min_duration_statement` to `-1`, which disables logging statement durations, and enable `log_duration`.

Enabling `log_min_duration_statement` will add reports about slowest queries and queries that took the most time. Note that if you set `log_statement` to `all`, the setting of `log_min_duration_statement` will have no effect.

Warning

Avoid setting `log_min_duration_statement` to a non-positive value together with enabling `log_duration` and `log_statement` as this will result in wrong counter values and drastically increase the size of your log. Always prefer setting `log_min_duration_statement`.

- Set the log line prefix string in `log_line_prefix`.

It must at least include a time escape sequence (`%t`, `%m` or `%n`) and the process-related escape sequence (`%p` or `%c`). For example, for `stderr` logs, the setting must be at least

```
log_line_prefix = '%t [%p]: '
```

The log line prefix could also specify the user, database name, application name and client IP address. For example,

for stderr logs:

```
log_line_prefix = '%t [%p]: user=%u,db=%d,app=%a,client=%h '
```

or

```
log_line_prefix = '%t [%p]: db=%d,user=%u,app=%a,client=%h '
```

and for syslog logs:

```
log_line_prefix = 'user=%u,db=%d,app=%a,client=%h '
```

or

```
log_line_prefix = 'db=%d,user=%u,app=%a,client=%h '
```

- To get more information from your log files, set certain configuration parameters as follows:

```
log_checkpoints = on
log_connections = on
log_disconnections = on
log_lock_waits = on
log_temp_files = 0
log_autovacuum_min_duration = 0
log_error_verbosity = default
```

To benefit from these settings, do not enable [log_statement](#) as pgbadger does not parse the corresponding log format.

- Set the language in which messages are displayed; messages must be in English with or without locale support:

```
lc_messages='C'
```

or

```
lc_messages='en_US.UTF-8'
```

Locales for other languages, such as `ru_RU.utf8`, are not supported.

Usage

The following are simple examples to illustrate miscellaneous pgbadger usage details.

```
pgbadger /var/lib/pgpro/std-16/data/log/postgresql-2022-01-14_000000.log
pgbadger /var/lib/pgpro/std-16/data/log/postgres.log.2.gz /var/lib/pgpro/std-16/data/
log/postgres.log.1.gz /var/lib/pgpro/std-16/data/log/postgresql-2022-01-14_000000.log
pgbadger /var/lib/pgpro/std-16/data/log/postgresql/postgresql-2022-01-*
pgbadger --exclude-query="^(COPY|COMMIT)" /var/lib/pgpro/std-16/data/log/
postgresql-2022-01-14_000000.log
pgbadger -b "2022-01-25 10:56:11" -e "2022-01-25 10:59:11" /var/lib/pgpro/std-16/data/
log/postgresql-2022-01-25-0000.log
cat /var/lib/pgpro/std-16/data/log/postgresql-2022-01-14_000000.log | pgbadger -
# Log line prefix with stderr log output
pgbadger --prefix '%t [%p]: user=%u,db=%d,client=%h' /var/lib/pgpro/std-16/data/log/
postgresql-2022-08-21*
pgbadger --prefix '%m %u@d %p %r %a : ' /var/lib/pgpro/std-16/data/log/
postgresql-2022-08-21-0000.log
# Log line prefix with syslog log output
pgbadger --prefix 'user=%u,db=%d,client=%h,appname=%a' /var/lib/pgpro/std-16/data/log/
postgresql-2022-08-21*
# Use 8 CPUs to parse 10GB file faster
```

```
pgbadger -j 8 /var/lib/pgpro/std-16/data/log/postgresql-2022-08-21-0000.log
# Use a cron job to report errors weekly
30 23 * * 1 /usr/bin/pgbadger -q -w /var/lib/pgpro/std-16/data/log/
postgresql-2022-01*.log -o /var/www/pg_reports/pg_errors.html
```

Specifying Remote Log Files

Specify remote log files to parse using a URI. Supported protocols are HTTP[S] and [S]FTP. The `curl` command will be used to download the file, and the file will be parsed during download. The SSH protocol is also supported and will use the `ssh` command to get log files, as when the `--remote-host` option is used.

Use these URI notations for the remote log file:

```
pgbadger http://172.12.110.1//var/lib/pgpro/std-16/data/log/
postgresql-2022-01-14_000000.log
pgbadger ftp://username@172.12.110.14/postgresql-2022-01-14_000000.log
pgbadger ssh://username@172.12.110.14:2222//var/lib/pgpro/std-16/data/log/
postgresql-2022-01-14_000000.log*
```

You can parse a local Postgres Pro log and a remote [pgbouncer](#) log file together:

```
pgbadger /var/lib/pgpro/std-16/data/log/postgresql-2022-01-14_000000.log ssh://
username@172.12.110.14/pgbouncer.log
```

Parallel Processing

To enable parallel processing, specify the `-j N` option, where *N* is the number of cores to use.

Parallel processing in pgbadger follows the algorithm below:

```
For each log file
  chunk size = int(file size / N)
  look at start/end offsets of these chunks
  fork N processes and seek to the start offset of each chunk
    each process will terminate when the parser reaches the end offset of its chunk
    each process writes stats into a binary temporary file
  wait for all child processes to terminate
All binary temporary files generated will then be read and loaded into
memory to build the html output.
```

With this method, at start/end of chunks pgbadger may truncate or omit a maximum of *N* queries per log file, which is an insignificant gap if you have millions of queries in your log file. The chance that the query that you were looking for is lost is near zero, so this gap can be considered suitable. Most of the time the query is counted twice, but truncated.

When you have many small log files and many CPUs, it is faster to dedicate one core to one log file at a time. To enable this behavior, specify the `-J N` option instead. Using this method, you can be sure not to lose any queries in the reports. With 200 log files of 10 MB each, the `-J` option starts being really efficient with 8 cores.

Here is a benchmark done on a server with 8 CPUs and a single file of 9.5 GB.

Option	1 CPU	2 CPU	4 CPU	8 CPU
-j	1h41m18	50m25	25m39	15m58
-J	1h41m18	54m28	41m16	34m45

With 200 log files of 10 MB each, which is 2 GB in total, the results are slightly different:

Option	1 CPU	2 CPU	4 CPU	8 CPU
-j	1h41m18	50m25	25m39	15m58
-J	1h41m18	54m28	41m16	34m45

```
-j      | 20m15 | 9m56 | 5m20 | 4m20  
-J      | 20m15 | 9m49 | 5m00 | 2m40
```

So it is recommended to use the `-j` option unless you have hundreds of small log files and can use at least 8 CPUs.

Important

During parallel parsing, `pgbadger` generates a lot of temporary files named `tmp_pgbadgerXXXX.bin` in the `/tmp` directory and removes them at the end.

Building Incremental Reports

The following sample cron job builds a report every week with the incremental behavior assuming that your log file and HTML report are also rotated every week:

```
0 4 * * 1 /usr/bin/pgbadger -q `find /var/lib/pgpro/std-16/data/log/ -mtime -7 -name  
"postgresql.log*"` -o /var/www/pg_reports/pg_errors-`date +%F`.html -l /var/reports/  
pgbadger_incremental_file.dat
```

But better turn on `pgbadger`'s automatic building incremental reports by specifying the `-I/--incremental` option. In this mode, `pgbadger` builds one report per day and a cumulative report per week. The output is first built in the binary format and saved to the output directory, specified by the `-O/--outdir` option, and then daily and weekly reports are built in the HTML format with the main index file. The main index file shows a dropdown menu per week with a link to the week's report and links to daily reports for that week. For example, run `pgbadger` as follows with the file rotated daily:

```
0 4 * * * /usr/bin/pgbadger -I -q /var/lib/pgpro/std-16/data/log/postgresql/  
postgresql.log.1 -O /var/www/pg_reports/
```

You will have all daily and weekly reports. In this mode `pgbadger` will automatically create an incremental file in the output directory, so you do not have to use the `-l` option unless you want to change the path of that file. This means that you can run `pgbadger` in this mode every day on a log file rotated every week and it will not count the log entries twice. To save disk space, you may want to use the `-x/--extra-files` command-line option to force `pgbadger` to write CSS and JavaScript files to the output directory as separate files. The resources will then be loaded using script and link tags.

In the incremental mode, you can also specify the number of weeks to keep in the report by using the `-O/--retention` option:

```
/usr/bin/pgbadger --retention 2 -I -q /var/lib/pgpro/std-16/data/log/postgresql/  
postgresql.log.1 -O /var/www/pg_reports/
```

If `pg_dump` is scheduled to run at 23:00 and 13:00 every day, you can exclude these periods from the report as follows:

```
pgbadger --exclude-time "2013-09-.* (23|13):.*" postgresql.log
```

This will help avoid having `COPY` statements generated by `pg_dump` on top of the list of slowest queries. Alternatively, you can use `--exclude-appname "pg_dump"` to solve this problem in a simpler way.

Rebuilding Reports

To update all HTML reports after fixing a `pgbadger` report or adding a new feature to it, you can rebuild incremental reports. To rebuild all reports in the case a binary file is still available, run:

```
rm /path/to/reports/*.js  
rm /path/to/reports/*.css  
pgbadger -X -I -O /var/www/pg_reports/ --rebuild
```

This will also update all the resource files (JavaScript and CSS). Use the `-E/--explode` option if the reports were built with this option.

Building Monthly Reports

By default, in the incremental mode `pgbadger` only computes daily and weekly reports. To have monthly cumulative reports, you will need to use a separate command to specify the report to build. For example, to build a report for August 2021, run:

```
pgbadger -X --month-report 2021-08 /var/www/pg_reports/
```

This will add a link to the month name to the calendar view of incremental reports to look at the monthly report. The report for a current month can be run every day, and it is entirely rebuilt each time. The monthly report is not built by default because it could take too long. Like when rebuilding reports, if reports were built with the per-database option (`-E/--explode`), it must be used to build the monthly report:

```
pgbadger -E -X --month-report 2021-08 /var/www/pg_reports/
```

Choosing the Report File Format

The `pgbadger` report file format is determined by the extension of the file passed to the `-o/--outfile` option.

Use the binary format (`-o *.bin`) to create custom incremental and cumulative reports.

For example, to refresh a `pgbadger` report every hour from a daily log file, you can run the following commands every hour:

```
# Generate incremental data files in the binary format
pgbadger --last-parsed .pgbadger_last_state_file -o sunday/hourX.bin /var/lib/pgpro/
std-16/data/log/postgresql-Sun.log
# Build a fresh HTML report from the generated binary file
pgbadger sunday/*.bin
```

For another example, assume that you generate one log file per hour. To have reports rebuilt each time the log file is rotated, run:

```
pgbadger -o day1/hour01.bin /var/lib/pgpro/std-16/data/log/postgresql-2022-01-23_10.log
pgbadger -o day1/hour02.bin /var/lib/pgpro/std-16/data/log/postgresql-2022-01-23_11.log
pgbadger -o day1/hour03.bin /var/lib/pgpro/std-16/data/log/postgresql-2022-01-23_12.log
...
```

And to refresh the HTML report, for example, each time after a new binary file is generated, just run:

```
pgbadger -o day1_report.html day1/*.bin
```

Adjust the commands to your particular needs.

Use the JSON format (`-o *.json`) to share data with other languages and to facilitate integration of `pgbadger` output with other monitoring tools, such as Cacti or Graphite.

Select other output formats to meet your particular needs. For example, this command will generate *Tsung* sessions XML file for `SELECT` queries only:

```
pgbadger -S -o sessions.tsung --prefix '%t [%p]: user=%u,db=%d ' /var/lib/pgpro/
std-16/data/log/postgresql-2022-01-14_000000.log
```

Return Codes

`pgbadger` return codes depend on how it terminated as follows:

- 0: was a success
- 1: died on error
- 2: has been interrupted using `Ctrl+C`, for example
- 3: the PID file already exists or cannot be created

- 4: no log file was specified on the command line

Options

This section describes pgbadger command-line options.

`-a minutes`

`--average minutes`

Specifies the number of minutes for which to build average graphs of queries and connections.

Default: 5.

`-A minutes`

`--histo-average minutes`

Specifies the number of minutes for which to build histogram graphs of queries.

Default: 60.

`-b datetime`

`--begin datetime`

Timestamp or time that specifies the start date/time for the data to be parsed in logs.

`-c host`

`--dbclient host`

Only report on log entries for the specified client host.

`-C`

`--nocomment`

Remove `/* ... */` comments from queries.

`-d name`

`--dbname name`

Only report on log entries for the specified database.

`-D`

`--dns-resolv`

Replace client IP addresses with their DNS names.

Warning

This can considerably slow down pgbadger.

`-e datetime`

`--end datetime`

Timestamp or time that specifies the end date/time for the data to be parsed in logs.

`-E`

`--explode`

Build one report per each database. Global information not related to any database gets added to the postgres database report.

`-f logtype`

`--format logtype`

Specifies the log type.

Possible values: syslog, syslog2, stderr, jsonlog, csv, pgbouncer, logplex, rds and redshift. Use when pgbadger cannot detect the log format.

- G
--nograph
Disables graphs in HTML output.
- h
--help
Show detailed information about pbadger options and exit.
- H *path*
--html-outdir *path*
Specifies the path to the directory where the HTML report must be written in the incremental mode. Note that binary files remain in the directory specified by -O/--outdir.
- i *name*
--ident *name*
Specifies the program name used to identify Postgres Pro messages in syslog logs.
Default: postgres.
- I
--incremental
Use the incremental mode, where reports will be generated by days in a separate directory specified by the -O/--outdir option.
- j *number*
--jobs *number*
Specifies the number of jobs to run at the same time. When working with csvlog logs, pgbadger always runs as single job.
Default: 1.
- J *number*
--Jobs *number*
Specifies the number of log files to parse in parallel.
Default: 1.
- l *filename*
--last-parsed *filename*
Specifies the file where the last datetime and line parsed are registered to allow incremental log parsing. Useful to watch errors since the last run or to get one report per day with the log rotated weekly.
- L *filename*
--logfile-list *filename*
Specifies the file containing the list of log files to parse.
- m *size*
--maxlength *size*
Specifies the maximum length of a query in reports. Longer queries will be truncated.

Default: 100000.

-M
--no-multiline

Turns off collecting multiline statements to avoid reporting excessive information, especially on errors that generate a huge report.

-N *name*
--appname *name*

Only report on log entries for the specified application.

-o *filename*
--outfile *filename*

Specifies the filename for the output and determines the report file format: `out.html`, `out.txt`, `out.bin` or `out.json`. Can be used multiple times to output several formats. For the `json` output, ensure that the Perl module `JSON::XS` is installed. To dump the output to stdout, use the value of `"-"` as filename.

Default: `out.html`, `out.txt`, `out.bin`, `out.json` or `out.tsung`,
for the respective output format.

-O *path*
--outdir *path*

Specifies the directory where out files must be saved.

-p *string*
--prefix *string*

Specifies the value of your custom `log_line_prefix` string, as defined in your `postgresql.conf`. Only use if your log line prefix is different from the standard `log_line_prefix` strings, for example, if your prefix includes additional variables, such as client IP or application name. The string must contain escape sequences for time (`%t`, `%m` or `%n`) and processes (`%p` or `%c`).

-P
--no-prettify

Disables SQL query code prettifier.

-q
--quiet

Disables printing anything to stdout, even the progress bar.

-Q
--query-numbering

Add numbering of queries to the output when used together with `--dump-all-queries` or `--normalized-only`.

-r *address*
--remote-host *address*

Specifies the host to execute the `cat` command on a remote log file to parse the file locally.

-R *number*
--retention *number*

Specifies the number of weeks for which to keep reports in the output directory in the incremental mode. The directories for older weeks and days are automatically removed.

Default: 0 (no reports are removed).

`-s number`
`--sample number`

Specifies the number of query samples to store.

Default: 3.

`-S`
`--select-only`

Only report on SELECT queries.

`-t number`
`--top number`

Specifies the number of queries to store/display.

Default: 20.

`-T string`
`--title string`

Specifies the title of the HTML report page.

`-u username`
`--dbuser username`

Only report on log entries for the specified username.

`-U username`
`--exclude-user username`

Specifies the username to exclude log entries for from the report. Can be used multiple times.

`-v`
`--verbose`

Enables the verbose or debug mode.

Default: off.

`-V`
`--version`

Show pgbadger version and exit.

`-w`
`--watch-mode`

Only report errors, just like [Logwatch](#) can do.

`-W`
`--wide-char`

Encode HTML output of queries in UTF8 to avoid Perl messages “Wide character in print”.

`-x format`
`--extension format`

Specifies the output format. Possible values: text, html, bin or json.

Default: html.

`-X`
`--extra-files`
In the incremental mode, write CSS and JavaScript resources to the output directory as separate files.

`-z command`
`--zcat command`
Specifies the full command to run the zcat program. Use if zcat, bzip or unzip is outside of your PATH directories.

`-Z +/-XX`
`--timezone +/-XX`
Specifies the number of hours from GMT for the timezone. Use to adjust date/time in JavaScript graphs. The value can be an integer (e.g., 2), or a float, (e.g., 2.5).

`--pie-limit number`
Specifies the number such that instead of lower pie data the sum will be shown.

`--exclude-query regexp`
Specifies the regular expression such that matching queries will be excluded from the report. For example: “^(VACUUM|COMMIT)”. Can be used multiple times.

`--exclude-file filename`
Specifies the path to the file that contains each regular expression to use to exclude matching queries from the report, one expression per line.

`--include-query regexp`
Specifies the regular expression such that only matching queries will be included in the report. Can be used multiple times. For example: “(tbl1|tbl2)”.

`--include-file filename`
Specifies the path to the file that contains each regular expression to use to include matching queries in the report, one expression per line.

`--disable-error`
Turns off generation of an error report.

`--disable-hourly`
Turns off generation of an hourly report.

`--disable-type`
Turns off generation of a report on queries by type, database and user.

`--disable-query`
Turns off generation of query reports, such as slowest or most frequent queries, queries by users, by database and so on.

`--disable-session`
Turns off generation of a session report.

`--disable-connection`
Turns off generation of a connection report.

`--disable-lock`
Turns off generation of a lock report.

`--disable-temporary`

Turns off generation of a report on temporary files.

`--disable-checkpoint`

Turns off generation of checkpoint/restartpoint reports.

`--disable-autovacuum`

Turns off generation of an autovacuum report.

`--charset name`

Specifies the HTML charset to be used.

Default: utf-8.

`--csv-separator char`

Specifies the CSV field separator.

Default: “,”.

`--exclude-time regexp`

Specifies the regular expression such that log entries for any matching timestamp will be excluded from the report. For example: “2013-04-12 .*”. Can be used multiple times.

`--include-time regexp`

Specifies the regular expression such that log entries for any matching timestamp will be included in the report. For example: “2013-04-12 .*”. Can be used multiple times.

`--exclude-db name`

Specifies the name of the database to exclude related log entries from the report. For example: “outdated_db”. Can be used multiple times.

`--exclude-appname name`

Specifies the name of the application to exclude related log entries from the report. For example: “pg_dump”. Can be used multiple time.

`--exclude-line regexp`

Specifies the regular expression such that any matching log entry will be excluded from the report. Can be used multiple times.

`--exclude-client name`

Specifies the client IP/name to exclude related log entries from the report. Can be used multiple times.

`--anonymize`

Obscure all literals in queries. Useful to hide confidential data.

`--noreport`

Prevents generation of reports in the incremental mode.

`--log-duration`

Associate log entries generated by `log_duration = on` and `log_statement = all`.

`--enable-checksum`

Add the MD5 sum under each query report.

`--journalctl command`

Specifies the command to produce the information similar to what the Postgres Pro log file contains. Usually, like this: `journalctl -u postgrespro-std-16`.

`--pid-dir path`

Specifies the path to store the PID file.

Default: `/tmp`.

`--pid-file filename`

Specifies the name of the PID file to manage concurrent execution of `pgbadger`.

Default: `pgbadger.pid`.

`--rebuild`

Rebuild all HTML reports in incremental output directories that contain binary data files.

`--pgbouncer-only`

Only show [pgbouncer](#)-related menus in the header.

`--start-monday`

In the incremental mode, start calendar weeks on Monday. By default, they start on Sunday.

`--iso-week-number`

In the incremental mode, start calendar weeks on Monday (by default, they start on Sunday) with ISO 8601 week numbering: 01 to 53, where week 1 is the first week of a year that has at least 4 days.

`--normalized-only`

Only dump all normalized queries to `out.txt`.

`--log-timezone +/-XX`

Specifies the number of hours from GMT for the timezone to adjust date/time read from the log file before parsing. The use of this option makes log search with date/time more complicated. The value can be an integer (e.g., 2), or a float, (e.g., 2.5).

`--prettify-json`

Prettify JSON output.

`--month-report YYYY-MM`

Specifies the month (YYYY-MM) to create a cumulative HTML report for. Requires incremental output directories to be set and all the necessary binary data files available.

`--day-report YYYY-MM-DD`

Specifies the day (YYYY-MM-DD) to create an HTML report for. Requires incremental output directories to be set and all the necessary binary data files available.

`--noexplain`

Avoid processing log lines generated by [auto_explain](#).

`--command cmd`

Specifies the command to run to retrieve log entries on stdin. `pgbadger` will open a pipe to this command and parse log entries that it generates.

`--no-week`

Avoid building weekly reports in the incremental mode. Use if building weekly reports takes too long.

`--explain-url URL`

Specifies the URL to override the URL of the graphical explain tool.

Default: <http://explain.depesz.com/>

`--tmpdir path`

Specifies the directory for temporary files.

Default: `File::Spec->tmpdir() || '/tmp'`.

`--no-process-info`

Disables changing the pgbadger process title to help identify this process. Useful for systems where changing process titles is not supported.

`--dump-all-queries`

Dump all queries found in the log file to a text file, replacing bind parameters in the queries at their respective placeholder positions.

`--keep-comments`

Retains comments in normalized queries. Useful to distinguish between same normalized queries.

`--no-progressbar`

Disables displaying the progress bar.

`--dump-raw-csv`

Parse the log and dump the information into CSV format. No further processing is done, no report.

`--include-pid PID`

Only report events related to the session PID (%p). Can be used multiple times.

`--include-session ID`

Only report events related to the session ID (%c). Can be used multiple times.

`--histogram-query VAL`

Use custom inbound for query time histogram. Default inbound in milliseconds: 0,1,5,10,25,50,100,500,1000,10000.

`--histogram-session VAL`

Use custom inbound for session time histogram. Default inbound in milliseconds: 0,500,1000,30000,60000,600000,1800000,3600000,28800000.

Remote Log Connection Options

pgbadger can parse a remote log file fetched using passwordless SSH connection. Use the `-r/--remote-host` option to set the IP address or name of the target host. More options to define SSH connection parameters are as follows:

`--ssh-program ssh`

Specifies the path to the SSH program to use.

Default: `ssh`.

`--ssh-port port`

Specifies the SSH port for the connection.

Default: 22.

`--ssh-user username`

Specifies the username for the connection.

Default: user running pgbadger.

`--ssh-identity filename`

Specifies the path to the identity file.

`--ssh-timeout seconds`

Specifies the timeout in seconds in case of the SSH connection failure.

Default: 10.

`--ssh-option options`

Specifies the list of options to define SSH connection parameters. The following options are always used:

`-o ConnectTimeout=$ssh_timeout -o PreferredAuthentications=hostbased,publickey`

`-o PreferredAuthentications=hostbased,publickey`

pg_repack

pg_repack — utility and Postgres Pro Standard extension to reorganize tables

Synopsis

```
pg_repack [option...] [dbname]
```

Description

pg_repack is a Postgres Pro Standard extension which lets you remove bloat from tables and indexes, and optionally restore the physical order of clustered indexes. Unlike `CLUSTER` and `VACUUM FULL` it works online, without holding an exclusive lock on the processed tables during processing. *pg_repack* is efficient to boot, with performance comparable to using `CLUSTER` directly.

pg_repack is a fork of the previous https://github.com/reorg/pg_reorg project.

You can choose one of the following methods to reorganize data:

- Online `CLUSTER` (ordered by cluster index)
- Ordering by specified columns
- Online `VACUUM FULL` (packing rows only)
- Rebuild or relocate only the indexes of a table

Note

Only superusers can use the utility.

Note

Target table must have a PRIMARY KEY, or at least a UNIQUE total index on a NOT NULL column.

Installation

On Linux systems, *pg_repack* is provided together with Postgres Pro Standard as a separate pre-built package `pg-repack-std-16` and requires the `postgrespro-std-16-server` package to be installed with all the dependencies. For the list of available packages and detailed installation instructions, see [Chapter 16](#). On Windows systems, *pg_repack* is automatically installed as part of Postgres Pro.

Once you have *pg_repack* installed, load the *pg_repack* extension in the database you want to process, as follows:

```
$ psql -c "CREATE EXTENSION pg_repack" -d your_database
```

You can later remove *pg_repack* from a Postgres Pro installation using `DROP EXTENSION pg_repack`.

If you are upgrading from a previous version of *pg_repack*, just drop the old version from the database as explained above and install the new version.

Options

Reorganization Options

```
-a  
--all
```

Attempt to repack all the databases of the cluster. Databases where the *pg_repack* extension is not installed will be skipped.

`-t table`
`--table=table`

Reorganize the specified table(s) only. Multiple tables may be reorganized by writing multiple `-t` switches. By default, all eligible tables in the target databases are reorganized.

`-I table`
`--parent-table=table`

Reorganize both the specified table(s) and its inheritors. Multiple table hierarchies may be reorganized by writing multiple `-I` switches.

`-c schema`
`--schema=schema`

Repack the tables in the specified schema(s) only. Multiple schemas may be repacked by writing multiple `-c` switches. Can be used in conjunction with `--tablespace` to move tables to a different tablespace.

`-o column[, ...]`
`--order-by=column[, ...]`

Perform an online `CLUSTER` ordered by the specified columns.

`-n`
`--no-order`

Perform an online `VACUUM FULL`. Since version 1.2 this is the default for non-clustered tables.

`-N`
`--dry-run`

Show what would be repacked and exit.

`-j num_jobs`
`--jobs=num_jobs`

Create the specified number of extra connections to Postgres Pro, and use these extra connections to parallelize the rebuild of indexes on each table. Parallel index builds are only supported for full-table repacks, not with `--index` or `--only-indexes` options. If your server has extra cores and disk I/O available, this can be a useful way to speed up `pg_repack`.

`-s tablespace`
`--tablespace=tablespace`

Move the repacked tables to the specified tablespace: essentially an online version of `ALTER TABLE ... SET TABLESPACE`. The tables' indexes are left in the original tablespace unless `--moveidx` is specified too.

`-S`
`--moveidx`

Also move the indexes of the repacked tables to the tablespace specified by the `--tablespace` option.

`-i index`
`--index=index`

Repack the specified index(es) only. Multiple indexes may be repacked by writing multiple `-i` switches. May be used in conjunction with `--tablespace` to move the index(es) to a different tablespace.

`-x`
`--only-indexes`

Repack only the indexes of the specified table(s), which must be specified with the `--table` option.

`-T secs`

`--wait-timeout=secs`

`pg_repack` needs to take an exclusive lock at the end of the reorganization. This setting controls how many seconds `pg_repack` will wait to acquire this lock. If the lock cannot be taken after this duration and `--no-kill-backend` option is not specified, `pg_repack` will forcibly cancel the conflicting queries. If you are using Postgres Pro or PostgreSQL version 8.4 or newer, `pg_repack` will fall back to using `pg_terminate_backend()` to disconnect any remaining backends after this timeout has passed twice. The default is 60 seconds.

`-D`

`--no-kill-backend`

Skip repacking a table if the lock cannot be taken for duration specified in `--wait-timeout`, instead of cancelling conflicting queries. The default is `false`.

`-Z`

`--no-analyze`

Disable `ANALYZE` after a full-table reorganization. If not specified, `ANALYZE` is executed after the reorganization.

`-k`

`--no-superuser-check`

Skip the superuser checks in the client. This setting is useful for using `pg_repack` on platforms that support running it as non-superusers.

`-C`

`--exclude-extension`

Skip tables that belong to the specified extension(s). Some extensions may heavily depend on such tables at planning time etc.

`--switch-threshold`

Switch tables when that many tuples are left in the log table. This setting can be used to avoid the inability to catch up with write-heavy tables.

Connection Options

Options to connect to servers. You cannot use `--all` and `--dbname` or `--table` or `--parent-table` together.

`-a`

`--all`

Reorganize all databases.

`[-d] dbname`

`[--dbname=] dbname`

Specifies the name of the database to be reorganized. If this is not specified and `-a` (or `--all`) is not used, the database name is read from the environment variable `PGDATABASE`. If that is not set, the user name specified for the connection is used.

`-h host`

`--host=host`

Specifies the host name of the machine on which the server is running. If the value begins with a slash, it is used as the directory for the Unix domain socket.

`-p port`

`--port=port`

Specifies the TCP port or local Unix domain socket file extension on which the server is listening for connections.

```
-U username
--username=username
```

User name to connect as.

```
-w
--no-password
```

Never issue a password prompt. If the server requires password authentication and a password is not available by other means such as a `.pgpass` file, the connection attempt will fail. This option can be useful in batch jobs and scripts where no user is present to enter a password.

```
-W
--password
```

Force `pg_repack` to prompt for a password before connecting to a database.

This option is never essential, since `pg_repack` will automatically prompt for a password if the server demands password authentication. However, `pg_repack` will waste a connection attempt finding out that the server wants a password. In some cases it is worth typing `-W` to avoid the extra connection attempt.

Generic Options

```
-e
--echo
```

Echo the commands that `pg_repack` generates and sends to the server.

```
-E level
--elevel=level
```

Choose the output message level from `DEBUG`, `INFO`, `NOTICE`, `WARNING`, `ERROR`, `LOG`, `FATAL`, and `PANIC`. The default is `INFO`.

```
--help
```

Show help about `pg_repack` command line arguments, and exit.

```
-V
--version
```

Print the `pg_repack` version and exit.

Environment

```
PGDATABASE
PGHOST
PGPORT
PGUSER
```

Default connection parameters

This utility, like most other Postgres Pro utilities, also uses the environment variables supported by `libpq` (see [Section 33.15](#)).

Examples

Perform an online `CLUSTER` of all the clustered tables in the database `test`, and perform an online `VACUUM FULL` of all the non-clustered tables:

```
$ pg_repack test
```

Perform an online `VACUUM FULL` on the tables `foo` and `bar` in the database `test` (an eventual cluster index is ignored):

```
$ pg_repack --no-order --table foo --table bar test
```

Move all indexes of table `foo` to tablespace `tbs`:

```
$ pg_repack -d test --table foo --only-indexes --tablespace tbs
```

Move the specified index to tablespace `tbs`:

```
$ pg_repack -d test --index idx --tablespace tbs
```

Diagnostics

Error messages are reported when `pg_repack` fails. The following list shows the cause of errors.

You need to cleanup by hand after fatal errors. To cleanup, just remove `pg_repack` from the database and install it again.

For Postgres Pro or PostgreSQL 9.1 and newer execute:

```
DROP EXTENSION pg_repack CASCADE
```

in the database where the error occurred, followed by

```
CREATE EXTENSION pg_repack
```

For previous versions load the script `$SHAREDIR/contrib/uninstall_pg_repack.sql` into the database where the error occurred and then load `$SHAREDIR/contrib/pg_repack.sql` again.

```
INFO: database "db" skipped:
```

```
pg_repack VER is not installed in the database:
```

```
pg_repack is not installed in the database when the --all option is specified.
```

Create the `pg_repack` extension in the database.

```
ERROR: pg_repack VER is not installed in the database:
```

```
pg_repack is not installed in the database specified by --dbname
```

Create the `pg_repack` extension in the database.

```
ERROR: program 'pg_repack V1' does not match database library 'pg_repack V2':  
There is a mismatch between the pg_repack binary and the database library  
(.so or .dll).
```

The mismatch could be due to the wrong binary in the `PATH` or the wrong database being addressed. Check the program directory and the database; if they are what expected you may need to repeat `pg_repack` installation.

```
ERROR: extension 'pg_repack V1' required, found 'pg_repack V2':
```

```
The SQL extension found in the database does not match the version required by the  
pg_repack program.
```

You should drop the extension from the database and reload it as described in [the section called “Installation”](#).

```
ERROR: relation "table" must have a primary key or not-null unique keys:
```

The target table doesn't have a PRIMARY KEY or any UNIQUE constraints defined.

Define a PRIMARY KEY or a UNIQUE constraint on the table.

```
ERROR: query failed: ERROR: column "col" does not exist:
The target table doesn't have columns specified by --order-by option.
```

Specify existing columns.

```
WARNING: the table "tbl" already has a trigger called z_repack_trigger:
The trigger was probably installed during a previous attempt
to run pg_repack on the table which was interrupted
and for some reason failed to clean up the temporary objects.
```

You can remove all the temporary objects by dropping and re-creating the extension: see [the section called “Installation”](#) for the details.

```
WARNING: trigger "trg" conflicting on table "tbl":
The target table has a trigger whose name follows z_repack_trigger
in alphabetical order.
```

The `z_repack_trigger` should be the last BEFORE trigger to fire. Please rename your trigger so that it sorts alphabetically before `pg_repack` one; you can use:

```
ALTER TRIGGER zzz_my_trigger
ON sometable RENAME TO yyy_my_trigger;
```

```
ERROR: Another pg_repack command may be running on the table. Please try again later.
```

There is a chance of deadlock when two concurrent `pg_repack` commands are run on the same table. So, try to run the command after some time.

```
WARNING: Cannot create index "schema"."index_xxxxx", already exists
DETAIL: An invalid index may have been left behind by a previous
pg_repack on the table which was interrupted. Please use DROP INDEX
"schema"."index_xxxxx" to remove this index and try again.
```

A temporary index apparently created by `pg_repack` has been left behind, and we do not want to risk dropping this index ourselves. If the index was in fact created by an old `pg_repack` job which didn't get cleaned up, you should just use `DROP INDEX` and try the `repack` command again.

Restrictions

`pg_repack` comes with the following restrictions.

Temporary tables

`pg_repack` cannot reorganize temporary tables.

GiST indexes

`pg_repack` cannot cluster tables by GiST indexes.

DDL commands

You will not be able to perform DDL commands of the target table(s) *except* `VACUUM` or `ANALYZE` while `pg_repack` is working. `pg_repack` will hold an `ACCESS SHARE` lock on the target table during a full-table repack, to enforce this restriction.

If you are using version 1.1.8 or earlier, you must not attempt to perform any DDL commands on the target table(s) while `pg_repack` is running. In many cases `pg_repack` would fail and rollback correctly, but there were some cases in these earlier versions which could result in data corruption.

[clusterdb](#), [vacuumdb](#)

I.3. Additional Postgres Pro Server Applications

This section covers additional Postgres Pro Standard server-related applications. They are typically run on the host where the database server resides. See also [Postgres Pro Server Applications](#) for information about server applications that are part of the core Postgres Pro Standard distribution.

mamonsu

mamonsu — a monitoring agent for collecting Postgres Pro and system metrics

Synopsis

```
mamonsu agent [agent_action]

mamonsu bootstrap -M mamonsu_user [-c | --config] [-x | --create-extensions] [connection_options]

mamonsu export {template | config} filename [export_options]

mamonsu report [report_options] [connection_options]

mamonsu tune [tuning_options] [connection_options]

mamonsu upload [upload_options]

mamonsu zabbix dashboard upload template_name

mamonsu zabbix {template | host | hostgroup} server_action

mamonsu zabbix item {error | lastvalue | lastclock} host_id

mamonsu zabbix version

mamonsu [-c | --config] [-d | --daemonize]

mamonsu --version

mamonsu --help
```

Description

mamonsu is a monitoring agent for collecting Postgres Pro and system metrics that can be visualized on the Zabbix server. Unlike the native Zabbix Agent configured to collect Postgres Pro metrics, mamonsu uses a single database connection, which allows to minimize performance impact on the monitored system.

The mamonsu agent includes the following components:

- A supervisor process that monitors database and system activity.
- Plugins that specify which Postgres Pro and system metrics to collect.
- Customizable configuration and template files that define which plugins to use and how to visualize the collected data.

mamonsu is an active agent, which means that it sends the data to the Zabbix server once it is collected. Pre-configured to monitor multiple Postgres Pro and system metrics out of the box, mamonsu can be extended with your own custom plugins to track other metrics critical for your system.

mamonsu also provides the command-line interface for updating some Zabbix server settings, as well as getting an overview of the monitored system configuration and tuning Postgres Pro and system settings on the fly. You can find the list of all mamonsu commands in [the section called “Command-Line Reference”](#).

Installation and Setup

Important

Before you start installation, attentively read [Compatibility Considerations](#).

To use `mamonsu`, you must create a Zabbix account and set up a Zabbix server as explained in [Zabbix documentation](#). Naturally, you must also have a Postgres Pro instance up and running if you are going to monitor Postgres Pro metrics. If you are configuring your Postgres Pro cluster from scratch, see [Chapter 16](#) and [Section 17.2](#) for Postgres Pro installation and setup instructions, respectively.

Note

While `mamonsu` can collect Postgres Pro metrics from a remote cluster, system metrics are only collected locally. If you choose to collect Postgres Pro metrics remotely, make sure to disable collection of system metrics to avoid confusion, as they will be displayed under the same host in Zabbix.

`mamonsu` is provided with Postgres Pro Standard as a separate pre-built package `mamonsu` (for the detailed installation instructions, see [Chapter 16](#)). Once you have installed `mamonsu`, complete the following steps to set up metrics collection:

1. Optionally, bootstrap `mamonsu`

If you omit this step, metrics can only be collected on behalf of a superuser, which is not recommended.

In this step, the `bootstrap` command sets the `mamonsu` user, creates `mamonsu` schema in the specified or implied database, as well as extensions and objects needed for monitoring.

`bootstrap` has no mandatory options. When run without options, it takes the values needed from the configuration file (`/etc/mamonsu/agent.conf` by default). Below is a simple example of `bootstrap`:

1. In the `[postgres]` section of `agent.conf`, specify connection parameters for the Postgres Pro cluster you are going to monitor. For more details, see [Connection Parameters](#).
2. Run the following command to bootstrap `mamonsu`:

```
mamonsu bootstrap
```

This command will create the user `mamonsu` with the password `mamonsu`, create monitoring functions in the database specified in `agent.conf` and grant the right to execute them to the `mamonsu` user.

In the following example, `bootstrap` options are passed explicitly.

1. Create a non-privileged database user for `mamonsu`. For example:

```
CREATE USER mamonsu_user WITH PASSWORD 'mamonsu_password';
GRANT pg_monitor TO mamonsu_user;
```

2. Create a database that will be used for connection to Postgres Pro. For example:

```
CREATE DATABASE mamonsu_database OWNER mamonsu_user;
```

3. Run the following command to bootstrap `mamonsu`:

```
mamonsu bootstrap -M mamonsu_user -x -c /etc/mamonsu/agent.conf -d
mamonsu_database -U postgres --host myhost --port 5432
```

For details of the options `-M`, `-x` and `-c`, see `bootstrap`. For details of other options, see [Connection Options](#). This command will create monitoring functions in the `mamonsu_database` and grant the right to execute them to `mamonsu_user`. The `pg_buffercache` extension will also be created to ensure collection of metrics on the shared buffer cache, and the path to the configuration file will be changed.

As a result, a superuser connection is no longer required. Note that `mamonsu` also creates several tables in the `mamonsu` schema in the specified database. Do not delete these tables as they are required for `mamonsu` to work.

2. Configure mamonsu

Edit the `agent.conf` configuration file, which is located in the `/etc/mamonsu/` directory by default.

- Configure Zabbix-related settings. The `address` field must point to the running Zabbix server, while the `client` field must provide the name of the Zabbix host. You can find the list of hosts available for your account in the Zabbix web interface under **Configuration > Hosts**.

```
[zabbix]
; enabled by default
enabled = True
client = zabbix_host_name
address = zabbix_server
```

- By default, mamonsu will collect both Postgres Pro and system metrics. If required, you can disable metrics collection of either type by setting the `enabled` parameter to `False` in the `[postgres]` or `[system]` section of the `agent.conf` file, respectively.

```
[system]
; enabled by default
enabled = True
```

Note

While mamonsu can collect Postgres Pro metrics from a remote cluster, system metrics are only collected locally. If you choose to collect Postgres Pro metrics remotely, make sure to disable collection of system metrics to avoid confusion, as they will be displayed under the same host in Zabbix.

- If you are going to collect Postgres Pro metrics, specify connection parameters for the Postgres Pro cluster you are going to monitor. In the `user`, `password`, and `database` fields, you must specify the `mamonsu_user`, `mamonsu_password`, and the `mamonsu_database` used for bootstrap, respectively. If you skipped the bootstrap, specify superuser credentials and the database to connect to.

```
[postgres]
; enabled by default
enabled = True
user = mamonsu_user
database = mamonsu_database
password = mamonsu_password
port = 5432
```

These are the main mamonsu settings to get started. You can also fine-tune other mamonsu settings as explained in [the section called “Configuration Parameters”](#).

3. Configure how to display metrics on the Zabbix server

1. Generate a template that defines how to visualize the collected metrics on the Zabbix server:

```
mamonsu export template template.xml
```

mamonsu generates the `template.xml` file in your current directory. By default, the name of the template that will be displayed in the Zabbix account is `PostgresPro-OS`, where `OS` is the name of your operating system. To get a template with a different display name, you can run the above command with the `--template-name` option.

2. Optionally, specify your Zabbix account settings in the following environment variables on your monitoring system:

- Set the `ZABBIX_USER` and `ZABBIX_PASSWD` variables to the login and password of your Zabbix account, respectively.
- Set the `ZABBIX_URL` to `http://zabbix/`

If you skip this step, you will have to add the following options to all `mamonsu zabbix` commands that you run:

```
--url=http://zabbix/ --user=zabbix_login --password=zabbix_password
```

3. Upload `template.xml` to the Zabbix server.

```
mamonsu zabbix template export template.xml
```

Alternatively, you can upload the template through the Zabbix web interface: log in to your Zabbix account and select **Templates > Import**.

4. Link the generated template to the host to be monitored.

In the Zabbix web interface, select your host, go to **Templates > Add**, select your template, and click **Update**.

Tip

If you would like to link a template with a new Zabbix host, you can do it from the command line using `mamonsu zabbix` commands. See [the section called “Managing Zabbix Server Settings from the Command Line”](#) for details.

When the setup is complete, start `mamonsu`. For example, on Linux systems, you can start `mamonsu` as a service with the following command:

```
service mamonsu start
```

`mamonsu` picks up all the parameters from the `mamonsu` configuration file and starts monitoring your system.

Command-Line Reference

agent

Syntax:

```
mamonsu agent { metric-list | metric-get metric_name | version }
```

Provide information on the collected metrics from the command line. You can specify one of the following parameters:

`metric-list`

Show the list of metrics that `mamonsu` is collecting. The output of this command provides the item key of each metric, its latest value, and the time when this value was received.

`metric-get metric_name`

Check the latest value for the specified metric. You can get the list of available metrics using the `metric-list` option.

`version`

Display `mamonsu` version.

bootstrap

Syntax:

```
mamonsu bootstrap -M mamonsu_user
                [-c[ config_file] | --config[=config_file]]
                [-x | --create-extensions] [connection_options]
```

Bootstrap mamonsu. This command can take the following options:

-M
Specify a non-privileged user that will own all mamonsu processes.

-c *config_file*
--config=*config_file*
Specify the `agent.conf` file where the `[postgres]` section contains the database name to be used if `--dbname` is not specified through *connection_options*.

Default: `/etc/mamonsu/agent.conf`

-x
--create-extensions
Create auxiliary extensions. The `pg_buffercache` extension will be created, which is no longer created by default. For Postgres Pro 12 or higher, the `bootstrap -x` command will also create functions to work with the `pgpro_stats` extension and grant the right to execute them to the `mamonsu` user.

connection_options
Provide optional *command-line connection parameters*.

export

Syntax:

```
mamonsu export config filename.conf [--add-plugins=plugin_directory]
mamonsu export template filename.xml [--add-plugins=plugin_directory]
                                     [--template-name=template_name]
                                     [--application=application_name]
                                     [--old-zabbix]
```

Generate a template or configuration file for metrics collection. The optional parameters to customize metrics collection are as follows:

--add-plugins=*plugin_directory*
Collect metrics that are defined in custom plugins located in the specified *plugin_directory*. If you are going to use custom plugins, you must provide this option when generating both the configuration file and the template.

--template-name=*template_name*
Specify the name of the template that will be displayed on the Zabbix server.

Default: `PostgresPro-OS`, where *OS* is the name of your operating system

--application=*application_name*
Specify an identifier under which the collected metrics will be displayed on the Zabbix server.

Default: `App-PostgresPro-OS`, where *OS* is the name of your operating system

--old-zabbix
Export a template for Zabbix server version 4.2 or lower. By default, the template is generated in a format compatible with Zabbix 4.4 or higher.

export zabbix-parameters

Syntax:

```
mamonsu export zabbix-parameters filename.conf [--add-plugins=plugin_directory]
                                           [--plugin-type={pg | sys | all}]
                                           [--pg-version=version]
                                           [--config=config_file]
```

Export metrics configuration for use with the native [Zabbix agent](#). The optional parameters to customize metrics collection are as follows:

`--add-plugins=plugin_directory`

Collect metrics that are defined in custom plugins located in the specified *plugin_directory*. If you are going to use custom plugins, you must provide this option when generating both the configuration file and the template.

`--plugin-type={pg | sys | all}`

Specify the type of metrics to collect:

- `pg` for Postgres Pro metrics.
- `sys` for system metrics.
- `all` for both Postgres Pro and system metrics.

Default: `all`

`--pg-version=version`

Specify the major version of the server for which to configure metrics collection. `mamonsu` can collect metrics for all supported Postgres Pro versions, as well as PostgreSQL versions starting from 9.5.

Default: `10`

`--config=config_file`

Specify the `agent.conf` file to be used as the source for metrics definitions.

Default: `/etc/mamonsu/agent.conf`

export zabbix-template

Syntax:

```
mamonsu export zabbix-template filename.conf [--add-plugins=plugin_directory]
                                           [--plugin-type={pg | sys | all}]
                                           [--template-name=template_name]
                                           [--application=application_name]
                                           [--config=config_file]
                                           [--old-zabbix]
```

Export a template for use with the native Zabbix agent. The optional parameters to customize metrics collection are as follows:

`--add-plugins=plugin_directory`

Collect metrics that are defined in custom plugins located in the specified *plugin_directory*. If you are going to use custom plugins, you must provide this option when generating both the configuration file and the template.

`--plugin-type={pg | sys | all}`

Specify the type of metrics to collect:

- `pg` configures Postgres Pro metrics.
- `sys` configures system metrics.
- `all` configures both Postgres Pro and system metrics.

Default: `all`

`--template-name=template_name`

Specify the name of the template that will be displayed on the Zabbix server.

Default: `PostgresPro-OS`, where *OS* is the name of your operating system

`--application=application_name`

Specify an identifier under which the collected metrics will be displayed on the Zabbix server.

Default: `App-PostgresPro-OS`, where *OS* is the name of your operating system

`--config=config_file`

Specify the `agent.conf` file to be used as the source for metrics definitions.

Default: `/etc/mamonsu/agent.conf`

`--old-zabbix`

Export a template for Zabbix server version 4.2 or lower. By default, the template is generated in a format compatible with Zabbix 4.4 or higher.

report

Syntax:

```
mamonsu report [--run-system=Boolean] [--run-postgres=Boolean]
               [--print-report=Boolean] [--report-path=report_file]
               [--disable-sudo] [connection_options]
```

Generate a detailed report on the hardware, operating system, memory usage and other parameters of the monitored system, as well as Postgres Pro configuration.

The following optional parameters customize the report:

`--run-system=Boolean`

Include system information into the generated report.

Default: `True`

`--run-postgres=Boolean`

Include information on Postgres Pro into the generated report.

Default: `True`

`--print-report=Boolean`

Print the report to stdout.

Default: `True`

`--report-path=report_file`

Save the report into the specified file.

Default: `/tmp/report.txt`

`--disable-sudo`

Do not report data that can only be received with superuser rights. This option is only available for Linux systems.

connection_options

Provide optional *command-line connection parameters*.

tune

Syntax:

```
mamonsu tune [--dry-run] [--disable-sudo] [--log-level {INFO|DEBUG|WARN}]
              [--dont-tune-pgbadger] [--dont-reload-postgresql]
              [connection_options]
```

Optimize Postgres Pro and system configuration based on the collected statistics. You can use the following options:

`--dry-run`

Display the settings to be tuned without changing the actual system and Postgres Pro configuration.

`--disable-sudo`

Do not tune the settings that can only be changed by a superuser. This option is only available for Linux systems.

`--dont-tune-pgbadger`

Do not tune *pgbadger* parameters.

`--log-level { INFO | DEBUG | WARN }`

Change the logging level.

Default: INFO

`--dont-reload-postgresql`

Forbid mamonsu to run the `pg_reload_conf()` function. If you specify this option, the modified settings that require reloading Postgres Pro configuration do not take effect immediately.

connection_options

Provide optional *command-line connection parameters*.

upload

Syntax:

```
mamonsu upload [--zabbix-file=metrics_file]
               [--zabbix-address=zabbix_address] [--zabbix-port=port_number]
               [--zabbix-client=zabbix_host_name] [--zabbix-log-level={INFO|DEBUG|
WARN}]
```

Upload metrics data previously saved into a file onto a Zabbix server for visualization. For details on how to save metrics into a file, see [the section called “Logging Parameters”](#).

This command can take the following options:

`--zabbix-address=zabbix_address`

The address of the Zabbix server.

Default: localhost

`--zabbix-port=port_number`

The port of the Zabbix server.

Default: 10051

`--zabbix-file=metrics_file`

A text file that stores the collected metrics data to be visualized, such as `localhost.log`.

`--zabbix-client=zabbix_host_name`

The name of the Zabbix host.

Default: `localhost`

`--zabbix-log-level={INFO|DEBUG|WARN}`

Change the logging level.

Default: `INFO`

zabbix dashboard upload

Syntax:

`mamonsu dashboard upload template_name`

Upload a Zabbix dashboard with the mamonsu metrics to a template on the Zabbix server version 6.0 or higher.

zabbix item

Syntax:

`mamonsu zabbix item {error | lastvalue | lastclock } host_name`

View the specified property of the latest metrics data received by Zabbix for the specified host.

zabbix version

Syntax:

`mamonsu zabbix version`

Get the version of the Zabbix server that mamonsu is connected to.

zabbix host

Syntax:

`mamonsu zabbix host list`

`mamonsu zabbix host show host_name`

`mamonsu zabbix host id host_name`

`mamonsu zabbix host delete host_id`

`mamonsu zabbix host create host_name hostgroup_id template_id mamonsu_address`

`mamonsu zabbix host info {templates | hostgroups | graphs | items} host_id`

Manage Zabbix hosts using one of the actions described in [the section called “Zabbix Server Actions”](#).

zabbix hostgroup

Syntax:

`mamonsu zabbix hostgroup list`

`mamonsu zabbix hostgroup show hostgroup_name`

`mamonsu zabbix hostgroup id hostgroup_name`

```
mamonsu zabbix hostgroup delete hostgroup_id
mamonsu zabbix hostgroup create hostgroup_name
```

Manage Zabbix host groups using one of the actions described in [the section called “Zabbix Server Actions”](#).

zabbix template

Syntax:

```
mamonsu zabbix template list
mamonsu zabbix template show template_name
mamonsu zabbix template id template_name
mamonsu zabbix template delete template_id
mamonsu zabbix template export file
```

Manage Zabbix templates using one of the actions described in [the section called “Zabbix Server Actions”](#).

[--config] [--daemonize]

Syntax:

```
mamonsu [-c config_file | --config=config_file]
        [-d | --daemonize]
```

Start working as a monitoring agent in the foreground or in the background using configuration parameters loaded from the configuration file. If the specified or default configuration file does not exist, exit with an error. Useful for debugging. You can specify the following options:

```
-c config_file
--config=config_file
```

Specify the `agent.conf` file where to load the configuration parameters from.

Default: `/etc/mamonsu/agent.conf`

```
-d
--daemonize
```

Run in the background. Without it, mamonsu will run in the foreground.

--version

Syntax:

```
mamonsu --version
```

Display mamonsu version.

--help

Syntax:

```
mamonsu --help
```

Display mamonsu command-line help.

Connection Options

connection_options provide command-line connection parameters for the target Postgres Pro cluster. *connection_options* can be `--host`, `--port`, `--dbname (-d)`, `--username (-U)`, and `--password (-W)`. The `--dbname` option should specify the *mamonsu_database* created for monitoring purposes. Note that the `--username (-U)` option must specify a superuser that can access the cluster.

If you omit *connection_options*, mamonsu checks the configuration file for the needed settings.

Zabbix Server Actions

Using `mamonsu`, you can control some of the Zabbix server functionality from the command line. Specifically, you can create or delete Zabbix hosts and host groups, as well as generate, import, and delete Zabbix templates using one of the following commands. The *object_name* to use must correspond to the type of the Zabbix object specified in the command: `template`, `host`, or `hostgroup`.

`list`

Display the list of available templates, hosts, or host groups.

`show object_name`

Display the details about the specified template, host, or host group.

`id object_name`

Show the ID of the specified object, which is assigned automatically by the Zabbix server.

`delete object_id`

Delete the object with the specified ID.

`create hostgroup_name`

`create host_name hostgroup_id template_id mamonsu_address`

Create a new host or a host group.

`export template_name`

Generate a Zabbix template.

`info {templates | hostgroups | graphs | items} host_id`

Display detailed information about the templates, host groups, graphs, and metrics available on the host with the specified ID.

Configuration Parameters

The `agent.conf` configuration file is located in the `/etc/mamonsu` directory by default. It provides several groups of parameters that control which metrics to collect and how to log the collected data:

- [connection parameters](#)
- [logging parameters](#)
- [plugin parameters](#)

All parameters must be specified in the `parameter = value` format.

Connection Parameters

[postgres]

The `[postgres]` section controls Postgres Pro metrics collection and can contain the following parameters:

`enabled`

Enables/disables Postgres Pro metrics collection if set to `True` or `False`, respectively.

Default: `True`

`user`

The user on behalf of which the cluster will be monitored. It must be the `mamonsu` user set in `bootstrap`, or a superuser if `bootstrap` was not run.

Default: postgres

password

The password for the specified user.

database

The database to connect to for metrics collection.

Default: postgres

host

The server address to connect to.

Default: localhost

port

The port to connect to.

Default: 5432

application_name

Application name that identifies mamonsu connected to the Postgres Pro cluster.

Default: mamonsu

query_timeout

[statement_timeout](#) for the mamonsu session, in seconds. If a Postgres Pro metric query does not complete within this time interval, it gets terminated.

Default: 10

Alternatively you can specify environment variables rather than the configuration parameters. The following environment variables can be used: PGUSER, PGPASSWORD, PGHOST, PGDATABASE, PGPORT, and PGAPPNAME. See [Section 33.15](#) for their meaning.

[system]

The [system] section controls system metrics collection and can contain the following parameters:

enabled

Enables/disables system metrics collection if set to True or False, respectively.

Default: True

[zabbix]

The [zabbix] section provides connection settings for the Zabbix server and can contain the following parameters:

enabled

Enables/disables sending the collected metrics data to the Zabbix server if set to True or False, respectively.

Default: True

client

The name of the Zabbix host.

address

The address of the Zabbix server.

Default: 127.0.0.1

port

The port of the Zabbix server.

Default: 10051

timeout

Maximum time to wait while connecting to the Zabbix server, in seconds.

Default: 15

[agent]

The `[agent]` section specifies the location of `mamonsu` and whether it is allowed to access metrics from the command line:

enabled

Enables/disables metrics collection from the command line using the `agent` command.

Default: `True`

host

The address of the system on which `mamonsu` is running.

Default: 127.0.0.1

port

The port on which `mamonsu` is running.

Default: 10052

[sender]

The `[sender]` section controls the queue size of the data to be sent to the Zabbix server:

queue

The maximum number of collected metric values that can be accumulated locally before `mamonsu` sends them to the Zabbix server. Once the accumulated data is sent, the queue is cleared.

Default: 2048

Logging Parameters

[metric_log]

The `[metric_log]` section enables storing the collected metrics data in text files locally. This section can contain the following parameters:

enabled

Enables/disables storing the collected metrics data in a text file. If this option is set to `True`, `mamonsu` creates the `localhost.log` file for storing metric values.

Default: `False`

directory

Specifies the directory where log files with metrics data will be stored.

Default: `/var/log/mamonsu`

`max_size_mb`

The maximum size of a log file, in MB. When the specified size is reached, it is renamed to `localhost.log.archive`, and an empty `localhost.log` file is created.

Default: 1024

[log]

The `[log]` section specifies logging settings for mamonsu and can contain the following parameters:

`file`

Specifies the log filename, which can be preceded by the full path.

`level`

Specifies the debug level. This option can take `DEBUG`, `ERROR`, or `INFO` values.

Default: `INFO`

`format`

The format of the logged data.

Default: `[% (levelname)s] %(asctime)s - %(name)s - %(message)s`

where `levelname` is the debug level, `asctime` returns the current time, `name` specifies the plugin that emitted this log entry or `root` otherwise, and `message` provides the actual log message.

Plugin Parameters

[plugins]

The `[plugins]` section specifies custom plugins to be added for metrics collection and can contain the following parameters:

`enabled`

Enables/disables using custom plugins for metrics collection if set to `True` or `False`, respectively.

Default: `False`

`directory`

Specifies the directory that contains custom plugins for metrics collection. Setting this parameter to `None` forbids using custom plugins.

Default: `/etc/mamonsu/plugins`

If you need to configure any of the plugins you add to mamonsu after installation, you have to add this plugin section to the `agent.conf` file.

The syntax of this section should follow the syntax used with the examples shown below in [the section called “Individual Plugin Sections”](#).

Individual Plugin Sections

All built-in plugins are installed along with mamonsu. To configure a built-in plugin you should find a corresponding section below the Individual Plugin Sections heading and edit its parameter values:

`enabled`

Enables/disables using built-in plugins if set to `True` or `False`, respectively. These values are case-sensitive.

Default: False

interval

Specifies the plugin operation interval, in seconds. The parameter is set with an integer specifying the plugin operation interval in seconds. You can set different intervals for different plugins. For plugins that collect PostgreSQL/ Postgres Pro metrics, for example, autovacuum, checkpoint, etc., this is the interval within which mamonsu accesses the Postgres Pro instance for metrics collection. For system plugins, for example, diskstats, memory, etc., this is the interval within which the operating system is accessed. For service plugins, for example, agentapi, logsender, zbxsender, this is the interval within which their functions are called. Note that the `interval` parameter of the `zbxsender` plugin is associated with the `timeout` parameter of the `[zabbix]` section. The maximum Zabbix server response timeout greater than the plugin operation interval may cause misbehavior of the `zbxsender` plugin: the plugin restarts with an error message if the connection or data transfer require longer time than the value specified in the `interval` parameter.

Default: 60

The example below shows individual plugin sections corresponding to the `preparedtransaction` and the `pgprobackup` built-in plugins:

```
[preparedtransaction]
max_prepared_transaction_time = 60
interval = 60

[pgprobackup]
enabled = false
interval = 300
backup_dirs = /backup_dir1,/backup_dir2
pg_probackup_path = /usr/bin/pg_probackup-11
```

[preparedtransaction]

This plugin gets age in seconds of the oldest prepared transaction and number of all transactions prepared for a two-phase commit. For additional information refer to [PREPARE TRANSACTION](#) and [Section 53.16](#).

The `max_prepared_transaction_time` parameter specifies the threshold in seconds for the age of the prepared transaction.

The plugin collects two metrics: `pgsql.prepared.count` (number of prepared transactions) and `pgsql.prepared.oldest` (oldest prepared transaction age in seconds).

If `pgsql.prepared.oldest` value exceeds the threshold specified by the `max_prepared_transaction_time` parameter, a trigger with the following message is fired: "PostgreSQL prepared transaction is too old on {host}".

[pgprobackup]

This plugin uses [pg_probackup](#) to track its backups' state and gets size of backup directories which store all backup files.

Please note that this plugin counts the total size of all files in the target directory. Make sure that extraneous files are not stored in this directory.

The `backup_dirs` parameter specifies a comma-separated list of paths to directories for which metrics should be collected.

The `pg_probackup_path` parameter specifies the path to `pg_probackup`.

By default this plugin is disabled. To enable it set the `enabled` parameter to `True`.

This plugin collects two metrics: `pg_probackup.dir.size[#backup_directory]` (the size of the target directory) and `pg_probackup.dir.error[#backup_directory]` (backup errors) for each specified `back-up_directory`.

If any generated backup has bad status, like `ERROR`, `CORRUPT`, `ORPHAN`, a trigger is fired.

Usage

Collecting and Viewing Metrics Data

Once started, `mamonsu` begins collecting system and Postgres Pro metrics. The `agent` command enables you to get an overview of the collected metrics from the command line in real time.

To view the list of available metrics, use the `agent metric-list` command:

```
mamonsu agent metric-list
```

The output of this command provides the item key of each metric, its latest value, and the time when this value was received. For example:

```
system.memory[active]          7921004544      1564570818
system.memory[swap_cache]      868352      1564570818
pgsql.connections[idle]        6.0        1564570818
pgsql.archive_command[failed_trying_to_archive] 0      1564570818
```

To view the current value for a specific metric, you can use the `agent metric-get` command:

```
mamonsu agent metric-get metric_name
```

where `metric_name` is the item key of the metric to monitor, as returned by the `metric-list` command. For example, `pgsql.connections[idle]`.

You can view graphs for the collected metrics in the Zabbix web interface under the **Graphs** menu. For details on working with Zabbix, see its official documentation at <https://www.zabbix.com/documentation/current/manual>.

If you have chosen to save all the collected metrics data into a file, as explained in [the section called “Logging Parameters”](#), you can later upload these metrics onto a Zabbix server for visualization using the `upload` command.

Adding Custom Plugins

You can extend `mamonsu` with your own custom plugins, as follows:

1. Save all custom plugins in a single directory, such as `/etc/mamonsu/plugins`.
2. Make sure this directory is specified in your configuration file under the `[plugins]` section:

```
[plugins]
directory = /etc/mamonsu/plugins
```

3. Generate a new Zabbix template to include custom plugins:

```
mamonsu export template template.xml --add-plugins=/etc/mamonsu/plugins
```

4. Upload the generated `template.xml` to the Zabbix server as explained in [the section called “Installation and Setup”](#).

Tuning Postgres Pro and System Configuration

Based on the collected metrics data, `mamonsu` can tune your Postgres Pro and system configuration for optimal performance.

You can get detailed information about the hardware, operating system, memory usage and other parameters of the monitored system, as well as Postgres Pro configuration, as follows:

```
mamonsu report
```

To view the suggested optimizations without applying them, run the `tune` command with the `--dry-run` option:

```
mamonsu tune --dry-run
```

To apply all the suggested changes, run the `tune` command without any parameters:

```
mamonsu tune
```

You can exclude some settings from the report or disable some of the optimizations by passing optional parameters. See [the section called “Command-Line Reference”](#) for the full list of parameters available for `report` and `tune` commands.

Managing Zabbix Server Settings from the Command Line

`mamonsu` enables you to work with the Zabbix server from the command line. You can upload template files to Zabbix, create and delete Zabbix hosts and host groups, link templates with hosts and check the latest metric values.

To set up your Zabbix host from scratch, you can follow these steps:

1. Optionally, specify your Zabbix account settings in the following environment variables on your monitoring system:
 - Set the `ZABBIX_USER` and `ZABBIX_PASSWD` variables to the login and password of your Zabbix account, respectively.
 - Set the `ZABBIX_URL` to `http://zabbix/`

If you skip this step, you will have to add the following options to all `mamonsu zabbix` commands that you run:

```
--url=http://zabbix/ --user=zabbix_login --password=zabbix_password
```

2. Generate a new template file and upload it to the Zabbix server:

```
mamonsu export template template.xml
mamonsu zabbix template export template.xml
```

3. Create a new host group:

```
mamonsu zabbix hostgroup create hostgroup_name
```

4. Check the IDs for this host group and the uploaded template, which are assigned automatically by the Zabbix server:

```
mamonsu zabbix hostgroup id hostgroup_name
mamonsu zabbix template id template_name
```

5. Create a host associated with this group and link it with the uploaded template using a single command:

```
mamonsu zabbix host create host_name hostgroup_id template_id mamonsu_address
```

where *host_name* is the name of the host, *hostgroup_id* and *template_id* are the unique IDs returned in the previous step, and *mamonsu_address* is the IP address of the system on which `mamonsu` runs.

Once your Zabbix host is configured, complete the setup of your monitoring system as explained in [the section called “Installation and Setup”](#).

Exporting Metrics for Native Zabbix Agent

Using `mamonsu`, you can convert system and Postgres Pro metrics definitions to the format supported by the native [Zabbix agent](#).

This feature currently has the following limitations:

- You cannot export metrics if you run `mamonsu` on Windows systems.
- Metrics definitions for `pg_wait_sampling` and CFS features available in Postgres Pro Enterprise are not converted.

Important

To work with Zabbix proxy, you must export settings to the format supported by the native Zabbix agent.

To collect metrics provided by `mamonsu` using the native Zabbix agent, do the following:

1. Generate a configuration file that is compatible with the native Zabbix agent and place it under `/etc/zabbix/zabbix_agent.d/`. You can prepend the filename with the required path:

```
mamonsu export zabbix-parameters /etc/zabbix/zabbix_agent.d/zabbix_agent.conf
```

For all possible options of the `export zabbix-parameters` command, see [the section called “Command-Line Reference”](#).
2. Generate a template for the native Zabbix agent:

```
mamonsu export zabbix-template template.xml
```

For all possible options of the `export zabbix-template` command, see [the section called “Command-Line Reference”](#).
3. Upload the generated template to the Zabbix server, as explained in [the section called “Installation and Setup”](#).
4. If you are going to collect Postgres Pro metrics, change the following macros in the template after the upload:
 - For `{$PG_CONNINFO}`, provide connection parameters for the Postgres Pro server to be monitored.
 - For `{$PG_PATH}`, specify `psql` installation directory.

Compatibility Considerations

If you want to upgrade `mamonsu` to a version that is not compatible with the previous one, what you must do to continue using the application depends on whether you need to retain the metrics data collected.

- If you need to retain the collected data, do the following:
 1. Install the new version of `mamonsu`.
 2. Generate a new template for the Zabbix server.
 3. If you performed a bootstrap using the previous version of `mamonsu`, run the `bootstrap` command again.
 4. Upload the new template to the Zabbix server.
 5. Rename the host for which you want to retain the collected data and leave the old template linked to that host.
 6. Create a new host for the same system and link the new template to it.
 7. Restart `mamonsu`. It will collect data for the new host. The old host will no longer be used, but the data collected will be available.
- If you do not need to retain the collected data, do the following:
 1. Install the new version of `mamonsu`.
 2. Generate a new template for the Zabbix server.

3. If you performed a bootstrap using the previous version of mamonsu, run the `bootstrap` command again.
4. Upload the new template to the Zabbix server.
5. In the settings of the Zabbix host, link the new template to the host instead of the old one.
6. Restart mamonsu. It will start collecting data. All the data collected earlier will be lost.

pgpro_controldata

`pgpro_controldata` — display control information of a PostgreSQL/Postgres Pro database cluster and compatibility information for a cluster and/or server

Synopsis

```
pgpro_controldata [option...]
```

Description

`pgpro_controldata` prints control information, such as the catalog version, initialized by `initdb` command of any PostgreSQL/Postgres Pro server. It also shows information about write-ahead logging and checkpoint processing. This information is cluster-wide and not specific to any database.

`pgpro_controldata` also helps to check compatibility between PostgreSQL/Postgres Pro database servers and clusters. It can print server or cluster parameters that can affect the compatibility and check whether a cluster and server are compatible by comparing those parameters.

`pgpro_controldata` is provided with Postgres Pro Standard as a separate pre-built package `pgpro-controldata` (for the detailed installation instructions, see [Chapter 16](#)).

Options

`pgpro_controldata` accepts the following command-line arguments. If no arguments are specified, `pgpro_controldata` just prints the control information like [pg_controldata](#) does. Note that compatibility-related command-line arguments `-P` and `-S` specified together work the same way as `-C`.

General-Purpose

`-B`
`--bindir`
Specifies the PostgreSQL/Postgres Pro executable directory, needed to get server compatibility parameters.

`-D datadir`
`--pgdata=datadir`
Specifies the file system location of the database configuration files. If this option is omitted, the environment variable `PGDATA` is used.

`-V`
`--version`
Print the `pgpro_controldata` version, then exit.

`-?`
`--help`
Show help about `pgpro_controldata` command-line arguments, then exit.

Compatibility-Related

`-C`
`--compatibility-check`
Display all parameters that can affect compatibility between the specified server and cluster and check whether they are compatible.

Use the `-D` option or the environment variable `PGDATA` to provide the path to the data directory, where read access is required.

If the `-B` option is omitted, the current server is assumed.

The cluster data and the server must have the same byte order and architecture type for this option to work correctly.

`-P`

`--cluster-compatibility-params`

Display all parameters of the specified cluster that can affect the compatibility.

Use the `-D` option or the environment variable `PGDATA` to provide the path to the data directory, where read access is required.

The cluster data and the server must have the same byte order and architecture type for this option to work correctly.

`-S`

`--server-compatibility-params`

Display all parameters of the specified or current server that can affect the compatibility.

If the `-B` option is omitted, the current server is assumed.

Environment

`PGDATA`

Default data directory location

`PG_COLOR`

Specifies whether to use color in diagnostic messages. Possible values are `always`, `auto` and `never`.

[pg_controldata](#)

pg_integrity_check

`pg_integrity_check` — calculate and validate checksums for controlled files (certified edition only)

Synopsis

```
pg_integrity_check [connection-option...] [-s | --system] [-u | --user] [-c | --catalog] [-o | --output]
[-l filename | --log=filename] [--syslog] [-D datadir] [-C filename] [-v | --verbose] [-? | --help]
```

Description

`pg_integrity_check` is a utility provided with Postgres Pro Standard that can calculate and validate checksums for the objects you would like to control. When running `pg_integrity_check`, you must specify at least one of the options that define the type of the controlled objects: `-s`, `-u`, or `-c` for read-only files, additional files, or system catalog tables, respectively.

If you use the `-o` option, `pg_integrity_check` calculates checksums and writes them into configuration files under the `share/security/` directory. You must have write access to the corresponding files to perform this command. You cannot use the `-o` option together with the `-s` option, since a checksum for read-only files cannot be overwritten.

If you omit the `-o` option, `pg_integrity_check` compares the calculated checksums with the corresponding checksums in the configuration files. If the checksums differ for any of the controlled objects, `pg_integrity_check` displays a message indicating the difference.

For details on using `pg_integrity_check`, see [Section 31.2](#).

Options

connection-options

Standard options for connecting to a database: `-d`, `-h`, `-p`, `-U`. You must specify `-d` and `-U` options when validating checksums for catalog tables with the `-c` option. For detailed description of connection options, see [psql](#).

`-s`
`--system`

Validate checksums for read-only files. Checksums for read-only files control both file contents and file attributes.

`-u`
`--user`

Validate checksums for additional files. Checksums for additional files control both file contents and file attributes.

`-c`
`--catalog`

Validate checksums for system catalog tables. For the `-c` option to work correctly, you must also specify connection parameters for the database. The database server must be started and accept connections.

`-o`
`--output`

Recalculate checksums and write it into a file.

`-l filename`
`--log=filename`

Write checksum validation results into a log file.

`--syslog`

Write checksum validation results into the syslog.

`-D datadir`

Data directory of the database cluster. This option is required to define the filenames for the generated configuration files when using `-u` option.

`-C filename`

The absolute path to the configuration file used for integrity checks of system catalog tables of the selected database. If used with the `-o` option, `pg_integrity_check` writes into the specified file. If no other option is used, `pg_integrity_check` checks data against the specified file.

`-v`

`--verbose`

Print debugging information, including checksum values.

`-?`

`--help`

Print command-line help.

Return Values

0 — checksums are calculated or validated successfully.

1 — an error occurred during the initial checksum calculation for read-only files.

2 — checksum validation revealed changes in one or more of the controlled objects.

3 — an unexpected error occurred during checksum validation.

Examples

Compute checksums for additional files and write them into the `share/security/_var_lib_pgpro_std-16_data.user.conf` configuration file:

```
pg_integrity_check -u -o -D /var/lib/pgpro/std-16/data
```

Check integrity of all controlled objects in the `postgres` database on behalf of the `postgres` user:

```
pg_integrity_check -s -u -c -D /var/lib/pgpro/std-16/data -d postgres -h localhost -p 5432 -U postgres
```

I.4. Third-Party Server Applications

This section covers third-party server-related applications. They are typically run on the host where the database server resides.

pgbouncer

pgbouncer — a Postgres Pro connection pooler

Synopsis

On Linux systems:

```
pgbouncer [ -d ] [ -R ] [ -v ] [ -u user ] pgbouncer.ini
```

```
pgbouncer -V | -h
```

On Windows:

```
pgbouncer [ -v ] [ -u user ] pgbouncer.ini
```

```
pgbouncer -V | -h
```

To use pgbouncer as a Windows service:

```
pgbouncer.exe --regservice pgbouncer.ini
```

```
pgbouncer.exe --unregservice pgbouncer.ini
```

Description

pgbouncer is a Postgres Pro connection pooler. Any target application can be connected to pgbouncer as if it were a Postgres Pro server, and pgbouncer will create a connection to the actual server, or it will reuse one of its existing connections.

The aim of pgbouncer is to lower the performance impact of opening new connections to Postgres Pro.

In order not to compromise transaction semantics for connection pooling, pgbouncer supports several types of pooling when rotating connections:

Session pooling

Most polite method. When a client connects, a server connection will be assigned to it for the whole duration the client stays connected. When the client disconnects, the server connection will be put back into the pool. This is the default method.

Transaction pooling

A server connection is assigned to a client only during a transaction. When pgbouncer notices that transaction is over, the server connection will be put back into the pool.

Statement pooling

Most aggressive method. The server connection will be put back into the pool immediately after a query completes. Multi-statement transactions are disallowed in this mode as they would break.

The administration interface of pgbouncer consists of some new `SHOW` commands available when connected to a special “virtual” database `pgbouncer`.

Quick Start

pgbouncer is provided with Postgres Pro Standard as a separate pre-built package `pgbouncer` (for the detailed installation instructions, see [Chapter 16](#)). Basic setup and usage is as follows.

1. Create a `pgbouncer.ini` file. Details in the `pgbouncer(5)` man page. Simple example:

```
[databases]
template1 = host=localhost dbname=template1 auth_user=someuser
```

```
[pgbouncer]
listen_port = 6432
listen_addr = localhost
auth_type = md5
auth_file = userlist.txt
logfile = pgbouncer.log
pidfile = pgbouncer.pid
admin_users = someuser
```

2. Create a `userlist.txt` file that contains the users allowed in:

```
"someuser" "same_password_as_in_server"
```

3. Launch `pgbouncer`:

```
$ pgbouncer -d pgbouncer.ini
```

Note

The above command does not work on Windows systems. Instead, `pgbouncer` must be launched as a service that first needs to be registered, as follows:

```
pgbouncer --regservice
```

4. Have your application (or the `psql` client) connect to `pgbouncer` instead of directly to the PostgreSQL server:

```
$ psql -p 6432 -U someuser template1
```

5. Manage `pgbouncer` by connecting to the special administration database `pgbouncer` and issuing `SHOW HELP`; to begin:

```
$ psql -p 6432 -U someuser pgbouncer
pgbouncer=# SHOW HELP;
NOTICE:  Console usage
DETAIL:
SHOW [HELP|CONFIG|DATABASES|FDS|POOLS|CLIENTS|SERVERS|SOCKETS|LISTS|VERSION|...]
SET key = arg
RELOAD
PAUSE
SUSPEND
RESUME
SHUTDOWN
[...]
```

6. If you made changes to the `pgbouncer.ini` file, you can reload it with:

```
pgbouncer=# RELOAD;
```

Options

`-d, --daemon`

Run in the background. Without it, the process will run in the foreground. In daemon mode, setting `pidfile` as well as `logfile` or `syslog` is required. No log messages will be written to `stderr` after going into the background.

Note

Does not work on Windows, `pgbouncer` needs to run as service there.

`-R, --reboot`

Note

This option is deprecated. Instead of this option use a rolling restart with multiple pgbouncer processes listening on the same port using `so_reuseport` instead.

Do an online restart. That means connecting to the running process, loading the open sockets from it, and then using them. If there is no active process, boot normally.

Note

Works only if OS supports Unix sockets and the `unix_socket_dir` is not disabled in configuration. Does not work on Windows. Does not work with TLS connections, they are dropped.

`-u user, --user user`

Switch to the given user on startup.

`-v, --verbose`

Increase verbosity. Can be used multiple times.

`-q, --quiet`

Be quiet: do not log to stderr. This does not affect logging verbosity, only that stderr is not to be used. For use in `init.d` scripts.

`-V, --version`

Show version.

`-h, --help`

Show short help.

`--regservice`

Win32: Register to run as Windows service. The `service_name` configuration parameter value is used as the name to register under.

`--unregservice`

Win32: Unregister Windows service.

Admin Console

The console is available by connecting as normal to the database pgbouncer:

```
$ psql -p 6432 pgbouncer
```

Only users listed in the configuration parameters `admin_users` or `stats_users` are allowed to log in to the console. (Except when `auth_mode=any`, then any user is allowed in as a `stats_user`.)

Additionally, the user name `pgbouncer` is allowed to log in without password, if the login comes via the Unix socket and the client has same Unix user uid as the running process.

The admin console currently only supports the simple query protocol. Some drivers use the extended query protocol for all commands; these drivers will not work for this.

Show Commands

The `SHOW` commands output information. Each command is described below.

SHOW STATS

Shows statistics. In this and related commands, the total figures are since process start, the averages are updated every `stats_period`.

database

Statistics are presented per database.

total_xact_count

Total number of SQL transactions pooled by pgbouncer.

total_query_count

Total number of SQL queries pooled by pgbouncer.

total_received

Total volume in bytes of network traffic received by pgbouncer.

total_sent

Total volume in bytes of network traffic sent by pgbouncer.

total_xact_time

Total number of microseconds spent by pgbouncer when connected to Postgres Pro in a transaction, either idle in transaction or executing queries.

total_query_time

Total number of microseconds spent by pgbouncer when actively connected to Postgres Pro, executing queries.

total_wait_time

Time spent by clients waiting for a server, in microseconds. Updated when a client connection is assigned a backend connection.

avg_xact_count

Average transactions per second in last stat period.

avg_query_count

Average queries per second in last stat period.

avg_recv

Average received (from clients) bytes per second.

avg_sent

Average sent (to clients) bytes per second.

avg_xact_time

Average transaction duration, in microseconds.

avg_query_time

Average query duration, in microseconds.

avg_wait_time

Average time spent by clients waiting for a server that were assigned a backend connection within the current `stats_period`, in microseconds (average per second within that period).

SHOW STATS_TOTALS

Subset of `SHOW STATS` showing the total values (`total_`).

SHOW STATS_AVERAGES

Subset of `SHOW STATS` showing the average values (`avg_`).

SHOW TOTALS

Like `SHOW STATS` but aggregated across all databases.

SHOW SERVERS

`type`

S, for server.

`user`

User name pgbouncer uses to connect to server.

`database`

Database name.

`state`

State of the pgbouncer server connection, one of `active`, `idle`, `used`, `tested`, `new`, `active_cancel`, or `being_canceled`.

`addr`

IP address of Postgres Pro server.

`port`

Port of Postgres Pro server.

`local_addr`

Connection start address on local machine.

`local_port`

Connection start port on local machine.

`connect_time`

When the connection was made.

`request_time`

When last request was issued.

`wait`

Not used for server connections.

`wait_us`

Not used for server connections.

`close_needed`

1 if the connection will be closed as soon as possible, because a configuration file reload or DNS update changed the connection information or `RECONNECT` was issued.

`ptr`

Address of internal object for this connection. Used as unique ID.

link

Address of client connection the server is paired with.

remote_pid

PID of backend server process. In case connection is made over Unix socket and OS supports getting process ID info, its OS PID. Otherwise it's extracted from cancel packet the server sent, which should be the PID in case the server is Postgres Pro, but it's a random number in case the server is another pgbouncer.

tls

A string with TLS connection information, or empty if not using TLS.

application_name

A string containing the `application_name` set on the linked client connection, or empty if this is not set, or if there is no linked connection.

SHOW CLIENTS

type

C, for client.

user

Client connected user.

database

Database name.

state

State of the client connection, one of `active`, `waiting`, `active_cancel_req`, or `waiting_cancel_req`.

addr

IP address of the client.

port

Source port of the client.

local_addr

Connection end address on local machine.

local_port

Connection end port on local machine.

connect_time

Timestamp of connect time.

request_time

Timestamp of latest client request.

wait

Current waiting time in seconds.

wait_us

Microsecond part of the current waiting time.

close_needed

Not used for clients.

ptr

Address of internal object for this connection. Used as unique ID.

link

Address of server connection the client is paired with.

remote_pid

Process ID, in case client connects over Unix socket and OS supports getting it.

tls

A string with TLS connection information, or empty if not using TLS.

application_name

A string containing the `application_name` set by the client for this connection, or empty if this is not set.

SHOW POOLS

A new pool entry is made for each couple of (database, user).

database

Database name.

user

User name.

cl_active

Client connections that are either linked to server connections or are idle with no queries waiting to be processed.

cl_waiting

Client connections that have sent queries but have not yet got a server connection.

cl_active_cancel_req

Client connections that have forwarded query cancellations to the server and are waiting for the server response.

cl_waiting_cancel_req

Client connections that have not forwarded query cancellations to the server yet.

sv_active

Server connections that are linked to a client.

sv_active_cancel

Server connections that are currently forwarding a cancel request.

sv_being_canceled

Servers that normally could become idle but are waiting to do so until all in-flight cancel requests have completed that were sent to cancel a query on this server.

sv_idle

Server connections that are unused and immediately usable for client queries.

sv_used

Server connections that have been idle for more than `server_check_delay`, so they need `server_check_query` to run on them before they can be used again.

sv_tested

Server connections that are currently running either `server_reset_query` or `server_check_query`.

sv_login

Server connections currently in the process of logging in.

maxwait

How long the first (oldest) client in the queue has waited, in seconds. If this starts increasing, then the current pool of servers does not handle requests quickly enough. The reason may be either an overloaded server or just too small of a `pool_size` setting.

maxwait_us

Microsecond part of the maximum waiting time.

pool_mode

The pooling mode in use.

SHOW PEER_POOLS

A new `peer_pool` entry is made for each configured peer.

database

ID of the configured peer entry.

cl_active_cancel_req

Client connections that have forwarded query cancellations to the server and are waiting for the server response.

cl_waiting_cancel_req

Client connections that have not forwarded query cancellations to the server yet.

sv_active_cancel

Server connections that are currently forwarding a cancel request.

sv_login

Server connections currently in the process of logging in.

SHOW LISTS

Show following internal information, in columns (not rows):

databases

Count of databases.

users

Count of users.

pools

Count of pools.

free_clients

Count of free clients.

used_clients

Count of used clients.

login_clients

Count of clients in login state.

free_servers

Count of free servers.

used_servers

Count of used servers.

dns_names

Count of DNS names in the cache.

dns_zones

Count of DNS zones in the cache.

dns_queries

Count of in-flight DNS queries.

dns_pending

Not used.

SHOW USERS

name

The user name.

pool_mode

The user's override `pool_mode`, or `NULL` if the default will be used instead.

SHOW DATABASES

name

Name of configured database entry.

host

Host pgbouncer connects to.

port

Port pgbouncer connects to.

database

Actual database name pgbouncer connects to.

`force_user`

When the user is part of the connection string, the connection between pgbouncer and Postgres Pro is forced to the given user, whatever the client user.

`pool_size`

Maximum number of server connections.

`min_pool_size`

Minimum number of server connections.

`reserve_pool`

Maximum number of additional connections for this database.

`pool_mode`

The database's override `pool_mode`, or `NULL` if the default will be used instead.

`max_connections`

Maximum number of allowed connections for this database, as set by `max_db_connections`, either globally or per database.

`current_connections`

Current number of connections for this database.

`paused`

1 if this database is currently paused, else 0.

`disabled`

1 if this database is currently disabled, else 0.

SHOW PEERS

`peer_id`

ID of the configured peer entry.

`host`

Host pgbouncer connects to.

`port`

Port pgbouncer connects to.

`pool_size`

Maximum number of server connections that can be made to this peer.

SHOW FDS

Internal command — shows list of file descriptors (FDs) in use with internal state attached to them.

When the connected user has the user name `pgbouncer`, connects through the Unix socket and has the same UID as the running process, the actual FDs are passed over the connection. This mechanism is used to do an online restart.

Note

This does not work on Windows.

This command also blocks the internal event loop, so it should not be used while pgbouncer is in use.

`fd`

File descriptor numeric value.

`task`

One of `pooler`, `client` or `server`.

`user`

User of the connection using the FD.

`database`

Database of the connection using the FD.

`addr`

IP address of the connection using the FD, `unix` if a Unix socket is used.

`port`

Port used by the connection using the FD.

`cancel`

Cancel key for this connection.

`link`

File descriptor for corresponding server/client. `NULL` if idle.

SHOW SOCKETS, SHOW ACTIVE_SOCKETS

Shows low-level information about sockets or only active sockets. This includes the information shown under `SHOW CLIENTS` and `SHOW SERVERS` as well as other more low-level information.

SHOW CONFIG

Show the current configuration settings, one per row, with the following columns:

`key`

Configuration variable name.

`value`

Configuration value.

`default`

Configuration default value.

`changeable`

Either `yes` or `no`, shows if the variable can be changed while running. If `no`, the variable can be changed only at boot-time. Use `SET` to change a variable at run time.

SHOW MEM

Shows low-level information about the current sizes of various internal memory allocations. The information presented is subject to change.

SHOW DNS_HOSTS

Show host names in DNS cache.

hostname

Host name.

ttl

How many seconds until next lookup.

addrs

Comma separated list of addresses.

SHOW DNS_ZONES

Show DNS zones in cache.

zonename

Zone name.

serial

Current serial.

count

Host names belonging to this zone.

SHOW VERSION

Show the pgbouncer version string.

SHOW STATE

Show the pgbouncer state settings. Current states are active, paused and suspended.

Process Controlling Commands

PAUSE [db]

pgbouncer tries to disconnect from all servers. Disconnecting each server connection waits for that server connection to be released according to the server pool's pooling mode (in transaction pooling mode, the transaction must complete, in statement mode, the statement must complete, and in session pooling mode the client must disconnect). The command will not return before all server connections have been disconnected. To be used at the time of database restart.

If database name is given, only that database will be paused.

New client connections to a paused database will wait until `RESUME` is called.

DISABLE db

Reject all new client connections on the given database.

ENABLE db

Allow new client connections after a previous `DISABLE` command.

RECONNECT db

Close each open server connection for the given database, or all databases, after it is released (according to the pooling mode), even if its lifetime is not up yet. New server connections can be made immediately and will connect as necessary according to the pool size settings.

This command is useful when the server connection setup has changed, for example to perform a gradual switchover to a new server. It is not necessary to run this command when the connection string in `pgbouncer.ini` has been changed and reloaded (see `RELOAD`) or when DNS resolution has changed,

because then the equivalent of this command will be run automatically. This command is only necessary if something downstream of pgbouncer routes the connections.

After this command is run, there could be an extended period where some server connections go to an old destination and some server connections go to a new destination. This is likely only sensible when switching read-only traffic between read-only replicas, or when switching between nodes of a multimas-ter replication setup. If all connections need to be switched at the same time, `PAUSE` is recommended instead. To close server connections without waiting (for example, in emergency failover rather than gradual switchover scenarios), also consider `KILL`.

KILL *db*

Immediately drop all client and server connections on given database.

New client connections to a killed database will wait until `RESUME` is called.

SUSPEND

All socket buffers are flushed and pgbouncer stops listening for data on them. The command will not return before all buffers are empty. To be used at the time of pgbouncer online reboot.

New client connections to a suspended database will wait until `RESUME` is called.

RESUME [*db*]

Resume work from previous `KILL`, `PAUSE`, or `SUSPEND` command.

SHUTDOWN

The pgbouncer process will exit.

RELOAD

The pgbouncer process will reload its configuration files and update changeable settings. This includes the main configuration file as well as the files specified by the settings `auth_file` and `auth_hba_file`.

pgbouncer notices when a configuration file reload changes the connection parameters of a database definition. An existing server connection to the old destination will be closed when the server connection is next released (according to the pooling mode), and new server connections will immediately use the updated connection parameters.

WAIT_CLOSE [*db*]

Wait until all server connections, either of the specified database or of all databases, have cleared the `close_needed` state (see [the section called “SHOW SERVERS”](#)). This can be called after a `RECONNECT` or `RELOAD` to wait until the respective configuration change has been fully activated, for example in switchover scripts.

Other Commands**SET *key* = *arg***

Changes a configuration setting (see also [the section called “SHOW CONFIG”](#)). For example:

```
SET log_connections = 1;
SET server_check_query = 'select 2';
```

(Note that this command is run on the pgbouncer admin console and sets pgbouncer settings. A `SET` command run on another database will be passed to the Postgres Pro backend like any other SQL command.)

Signals

`SIGHUP`

Reload config. Same as issuing the command `RELOAD` on the console.

SIGINT

Safe shutdown. Same as issuing `PAUSE` and `SHUTDOWN` on the console.

SIGTERM

Immediate shutdown. Same as issuing `SHUTDOWN` on the console.

SIGUSR1

Same as issuing `PAUSE` on the console.

SIGUSR2

Same as issuing `RESUME` on the console.

Libevent Settings

From the libevent documentation:

It is possible to disable support for `epoll`, `kqueue`, `devpoll`, `poll`, or `select` by setting the environment variable `EVENT_NOEPOLL`, `EVENT_NOKQUEUE`, `EVENT_NODEVPOLL`, `EVENT_NOPOLL` or `EVENT_NOSELECT`, respectively.

By setting the environment variable `EVENT_SHOW_METHOD`, libevent displays the kernel notification method that it uses.

pgbouncer.ini Configuration File

The configuration file is in the `.ini` format. Section names are between `[` and `]`. Lines starting with `;` or `#` are taken as comments and ignored. The characters `;` and `#` are not recognized as special when they appear later in the line.

Generic Settings

`logfile`

Specifies the log file. For daemonization (`-d`), either this or `syslog` has to be set. The log file is kept open, so after rotation, `kill -HUP` or on console `RELOAD;` should be done. On Windows, the service must be stopped and started.

Note that setting `logfile` does not by itself turn off logging to `stderr`. Use the command-line option `-q` or `-d` for that.

Default: not set

`pidfile`

Specifies the PID file. Without `pidfile` set, daemonization (`-d`) is not allowed.

Default: not set

`listen_addr`

Specifies a list (comma-separated) of addresses where to listen for TCP connections. You may also use `*` meaning "listen on all addresses". When not set, only Unix socket connections are accepted.

Addresses can be specified numerically (IPv4/IPv6) or by name.

Default: not set

`listen_port`

Which port to listen on. Applies to both TCP and Unix sockets.

Default: 6432

`unix_socket_dir`

Specifies the location for Unix sockets. Applies to both the listening socket and server connections. If set to an empty string, Unix sockets are disabled. A value that starts with @ specifies that a Unix socket in the abstract namespace should be created (currently supported on Linux and Windows).

For online reboot (-R) to work, a Unix socket needs to be configured, and it needs to be in the file-system namespace.

Default: /tmp (empty on Windows)

`unix_socket_mode`

File system mode for Unix socket. Ignored for sockets in the abstract namespace. Not supported on Windows.

Default: 0777

`unix_socket_group`

Group name to use for Unix socket. Ignored for sockets in the abstract namespace. Not supported on Windows.

Default: not set

`user`

If set, specifies the Unix user to change to after startup. Works only if pgbouncer is started as root or if it's already running as the given user.

Not supported on Windows.

Default: not set

`pool_mode`

Specifies when a server connection can be reused by other clients.

`session`

Server is released back to pool after client disconnects. Default.

`transaction`

Server is released back to pool after transaction finishes.

`statement`

Server is released back to pool after query finishes. Transactions spanning multiple statements are disallowed in this mode.

`max_client_conn`

Maximum number of client connections allowed.

When this setting is increased, then the file descriptor limits in the operating system might also have to be increased. Note that the number of file descriptors potentially used is more than `max_client_conn`. If each user connects under its own username to the server, the theoretical maximum used is:

`max_client_conn + (max pool_size * total databases * total users)`

If a database user is specified in the connection string (all users connect under the same user name), the theoretical maximum is:

`max_client_conn + (max pool_size * total databases)`

The theoretical maximum should never be reached, unless somebody deliberately crafts a special load for it. Still, it means you should set the number of file descriptors to a safely high number.

Search for `ulimit` in your favorite shell man page. Note: `ulimit` does not apply in a Windows environment.

Default: 100

`default_pool_size`

How many server connections to allow per user/database pair. Can be overridden in the per-database configuration.

Default: 20

`min_pool_size`

Add more server connections to pool if below this number. Improves the behavior when the normal load suddenly comes back after a period of total inactivity. The value is effectively capped at the pool size.

Default: 0 (disabled)

`reserve_pool_size`

How many additional connections to allow to a pool (see [reserve_pool_timeout](#)). The 0 value disables this parameter.

Default: 0 (disabled)

`reserve_pool_timeout`

If a client has not been serviced in this time, `pgbouncer` enables use of additional connections from the reserve pool. The 0 value disables this parameter. [seconds]

Default: 5.0

`max_db_connections`

Do not allow more than this many server connections per database (regardless of user). This considers the `pgbouncer` database that the client has connected to, not the Postgres Pro database of the outgoing connection. This can also be set per database in the `[databases]` section.

Note that when you hit the limit, closing a client connection to one pool will not immediately allow a server connection to be established for another pool, because the server connection for the first pool is still open. Once the server connection closes (due to idle timeout), a new server connection will immediately be opened for the waiting pool.

Default: 0 (unlimited)

`max_user_connections`

Do not allow more than this many server connections per user (regardless of database). This considers the `pgbouncer` user that is associated with a pool, which is either the user specified for the server connection or in absence of that the user the client has connected as. This can also be set per user in the `[users]` section.

Note that when you hit the limit, closing a client connection to one pool will not immediately allow a server connection to be established for another pool, because the server connection for the first pool is still open. Once the server connection closes (due to idle timeout), a new server connection will immediately be opened for the waiting pool.

Default: 0 (unlimited)

`server_round_robin`

By default, pgbouncer reuses server connections in LIFO (last-in, first-out) manner, so that few connections get the most load. This gives best performance if you have a single server serving a database. But if there is a round-robin system behind a database address (TCP, DNS, or host list), then it is better if pgbouncer also uses connections in that manner, thus achieving uniform load.

Default: 0

`track_extra_parameters`

By default, pgbouncer tracks `client_encoding`, `datestyle`, `timezone`, `standard_conforming_strings` and `application_name` parameters per client. To allow other parameters to be tracked, they can be specified here, so that pgbouncer knows that they should be maintained in the client variable cache and restored in the server whenever the client becomes active.

If you need to specify multiple values, use a comma-separated list (e.g. `default_transaction_read-only, IntervalStyle`)

Note

Most parameters cannot be tracked this way. The only parameters that can be tracked are ones that Postgres Pro reports to the client. Postgres Pro has [an official list of parameters that it reports to the client](#). Postgres Pro extensions can change this list though, they can add parameters themselves that they also report, and they can start reporting already existing parameters that Postgres Pro does not report. Notably Citus 12.0+ causes PostgreSQL to also report `search_path`.

The `postgres` protocol allows specifying parameter settings, both directly as a parameter in the startup packet, or inside the [options startup packet](#). Parameters specified using both of these methods are supported by `track_extra_parameters`. However, it's not possible to include `options` itself in `track_extra_parameters`, only the parameters contained in `options`.

Default: `IntervalStyle`

`ignore_startup_parameters`

By default, pgbouncer allows only parameters it can keep track of in startup packets: `client_encoding`, `datestyle`, `timezone` and `standard_conforming_strings`.

All other parameters will raise an error. To allow other parameters, they can be specified here, so that pgbouncer knows that they are handled by the admin and it can ignore them.

If you need to specify multiple values, use a comma-separated list (e.g. `options,extra_float_digits`).

The `postgres` protocol allows specifying parameter settings, both directly as a parameter in the startup packet, or inside the [options startup packet](#). Parameters specified using both of these methods are supported by `ignore_startup_parameters`. It's even possible to include `options` itself in `ignore_startup_parameters`, which results in any unknown parameters contained inside `options` to be ignored.

Default: empty

`peer_id`

The peer ID used to identify this pgbouncer process in a group of pgbouncer processes that are peered together. The `peer_id` value should be unique within a group of peered pgbouncer processes. When set to 0, pgbouncer peering is disabled. See also [\[peers\] Section](#) for more information. The maximum value that can be used for the `peer_id` is 16383.

Default: 0

`disable_pqexec`

Disable the Simple Query protocol (PQexec). Unlike the Extended Query protocol, Simple Query allows multiple queries in one packet, which allows some classes of SQL-injection attacks. Disabling it can improve security. Obviously, this means only clients that exclusively use the Extended Query protocol will stay working.

Default: 0

`application_name_add_host`

Add the client host address and port to the application name setting set on connection start. This helps in identifying the source of bad queries, etc. This logic applies only at the start of a connection. If `application_name` is later changed with `SET`, `pgbouncer` does not change it again.

Default: 0

`conffile`

Show location of current configuration file. Changing it will make `pgbouncer` use another configuration file for next `RELOAD` / `SIGHUP`.

Default: file from command line

`service_name`

Used on win32 service registration.

Default: `pgbouncer`

`job_name`

Alias for `service_name`.

`stats_period`

Sets how often the averages shown in various `SHOW` commands are updated and how often aggregated statistics are written to the log (but see `log_stats`). [seconds]

Default: 60

Authentication Settings

`pgbouncer` handles its own client authentication and has its own database of users. These settings control this.

`auth_type`

How to authenticate users.

`cert`

The client must connect over TLS connection with a valid client certificate. The user name is then taken from the `CommonName` field from the certificate.

`md5`

Use MD5-based password check. This is the default authentication method. `auth_file` may contain both MD5-encrypted and plain-text passwords. If `md5` is configured and a user has a SCRAM secret, then SCRAM authentication is used automatically instead.

`scram-sha-256`

Use password check with SCRAM-SHA-256. `auth_file` has to contain SCRAM secrets or plain-text passwords. Note that SCRAM secrets can only be used for verifying the password of a client

but not for logging into a server. To be able to use SCRAM on server connections, use plain-text passwords.

plain

The clear-text password is sent over the wire. Deprecated.

trust

No authentication is done. The user name must still exist in `auth_file`.

any

Like the `trust` method, but the user name given is ignored. Requires that all databases are configured to log in as a specific user. Additionally, the console database allows any user to log in as admin.

hba

The actual authentication type is loaded from `auth_hba_file`. This allows different authentication methods for different access paths, for example: connections over Unix socket use `peer` authentication method, connections over TCP must use TLS.

pam

Pluggable Authentication Modules (PAM) method is used to authenticate users, `auth_file` is ignored. This method is not compatible with databases using the `auth_user` option. The service name reported to PAM is `pgbouncer`. `pam` is not supported in the HBA configuration file.

auth_hba_file

HBA configuration file to use when `auth_type` is `hba`.

Default: not set

auth_file

The name of the file to load user names and passwords from. See [the section called “Authentication File Format”](#) for details.

Most authentication types (see `auth_type`) require that either `auth_file` or `auth_user` be set; otherwise there would be no users defined.

Default: not set

auth_user

If `auth_user` is set, then any user not specified in `auth_file` will be queried through the `auth_query` query from `pg_shadow` in the database, using `auth_user`. The password of `auth_user` will be taken from `auth_file`. (If `auth_user` does not require a password, then it does not need to be defined in `auth_file`.)

Direct access to `pg_shadow` requires admin rights. It's preferable to use a non-superuser that calls a `SECURITY DEFINER` function instead.

Default: not set

auth_query

Query to load user's password from database.

Direct access to `pg_shadow` requires admin rights. It's preferable to use a non-superuser that calls a `SECURITY DEFINER` function instead.

Note that the query is run inside the target database. So if a function is used, it needs to be installed into each database.

Default: `SELECT username, passwd FROM pg_shadow WHERE username=$1`

`auth_dbname`

Database name in the [\[databases\] section](#) to be used for authentication purposes. This option can be either global or overridden in the connection string if this parameter is specified.

Log Settings

`syslog`

Toggles syslog on/off. On Windows, the event log is used instead.

Default: 0

`syslog_ident`

Under what name to send logs to syslog.

Default: `pgbouncer` (program name)

`syslog_facility`

Under what facility to send logs to syslog. Possibilities: `auth`, `authpriv`, `daemon`, `user`, `local0-7`.

Default: `daemon`

`log_connections`

Log successful logins.

Default: 1

`log_disconnections`

Log disconnections with reasons.

Default: 1

`log_pooler_errors`

Log error messages the pooler sends to clients.

Default: 1

`log_stats`

Write aggregated statistics into the log, every [stats_period](#). This can be disabled if external monitoring tools are used to grab the same data from `SHOW` commands.

Default: 1

`verbose`

Increase verbosity. Mirrors the `-v` switch on the command line. For example, using `-v -v` on the command line is the same as `verbose=2`.

Default: 0

Console Access Control

`admin_users`

Comma-separated list of database users that are allowed to connect and run all commands on the console. Ignored when [auth_type](#) is `any`, in which case any user name is allowed in as admin.

Default: empty

`stats_users`

Comma-separated list of database users that are allowed to connect and run read-only queries on the console. That means all `SHOW` commands except `SHOW FDS`.

Default: empty

Connection Sanity Checks, Timeouts`server_reset_query`

Query sent to server on connection release, before making it available to other clients. At that moment no transaction is in progress, so the value should not include `ABORT` or `ROLLBACK`.

The query is supposed to clean any changes made to the database session so that the next client gets the connection in a well-defined state. The default is `DISCARD ALL`, which cleans everything, but that leaves the next client no pre-cached state. It can be made lighter, e.g. `DEALLOCATE ALL` to just drop prepared statements, if the application does not break when some state is kept around.

When transaction pooling is used, the `server_reset_query` is not used, because in that mode, clients must not use any session-based features, since each transaction ends up in a different connection and thus gets a different session state.

Default: `DISCARD ALL`

`server_reset_query_always`

Whether `server_reset_query` should be run in all pooling modes. When this setting is off (default), the `server_reset_query` will be run only in pools that are in sessions-pooling mode. Connections in transaction-pooling mode should not have any need for a reset query.

This setting is for working around broken setups that run applications that use session features over a transaction-pooled pgbouncer. It changes non-deterministic breakage to deterministic breakage: clients always lose their state after each transaction.

Default: 0

`server_check_delay`

How long to keep released connections available for immediate re-use, without running `server_check_query` on it. If 0 then the query is always run.

Default: 30.0

`server_check_query`

Simple do-nothing query to check if the server connection is alive.

If an empty string, then sanity checking is disabled.

Default: `select 1`

`server_fast_close`

Disconnect a server in session pooling mode immediately or after the end of the current transaction if it is in `close_needed` mode (set by `RECONNECT`, `RELOAD` that changes connection settings, or DNS change), rather than waiting for the session end. In statement or transaction pooling mode, this has no effect since that is the default behavior there.

If because of this setting a server connection is closed before the end of the client session, the client connection is also closed. This ensures that the client notices that the session has been interrupted.

This setting makes connection configuration changes take effect sooner if session pooling and long-running sessions are used. The downside is that client sessions are liable to be interrupted by a

configuration change, so client applications will need logic to reconnect and reestablish session state. But note that no transactions will be lost, because running transactions are not interrupted, only idle sessions.

Default: 0

`server_lifetime`

The pooler will close an unused (not currently linked to any client connection) server connection that has been connected longer than this. Setting it to 0 means the connection is to be used only once, then closed. [seconds]

Default: 3600.0

`server_idle_timeout`

If a server connection has been idle more than this many seconds it will be closed. If 0 then timeout is disabled. [seconds]

Default: 600.0

`server_connect_timeout`

If connection and login don't finish in this amount of time, the connection will be closed. [seconds]

Default: 15.0

`server_login_retry`

If login to the server failed, because of failure to connect or from authentication, the pooler waits this much before retrying to connect. During the waiting interval, new clients trying to connect to the failing server will get an error immediately without another connection attempt. [seconds]

The purpose of this behavior is that clients don't unnecessarily queue up waiting for a server connection to become available if the server is not working. However, it also means that if a server is momentarily failing, for example during a restart or if the configuration was erroneous, then it will take at least this long until the pooler will consider connecting to it again. Planned events such as restarts should normally be managed using the `PAUSE` command to avoid this.

Default: 15.0

`client_login_timeout`

If a client connects but does not manage to log in in this amount of time, it will be disconnected. Mainly needed to avoid dead connections stalling `SUSPEND` and thus online restart. [seconds]

Default: 60.0

`autodb_idle_timeout`

If the automatically created (via `"*`") database pools have been unused this many seconds, they are freed. The negative aspect of that is that their statistics are also forgotten. [seconds]

Default: 3600.0

`dns_max_ttl`

How long DNS lookups can be cached. The actual DNS TTL is ignored. [seconds]

Default: 15.0

`dns_nxdomain_ttl`

How long DNS errors and `NXDOMAIN` DNS lookups can be cached. [seconds]

Default: 15.0

`dns_zone_check_period`

Period to check if a zone serial has changed.

pgbouncer can collect DNS zones from host names (everything after first dot) and then periodically check if the zone serial changes. If it notices changes, all host names under that zone are looked up again. If any host IP changes, its connections are invalidated.

Default: 0.0 (disabled)

`resolv_conf`

The location of a custom `resolv.conf` file. This is to allow specifying custom DNS servers and perhaps other name resolution options, independent of the global operating system configuration.

The parsing of the file is done by the DNS backend library, not pgbouncer, so see the library's documentation for details on allowed syntax and directives.

Default: empty (use operating system defaults)

TLS Settings

`client_tls_sslmode`

TLS mode to use for connections from clients. TLS connections are disabled by default. When enabled, `client_tls_key_file` and `client_tls_cert_file` must be also configured to set up the key and certificate pgbouncer uses to accept client connections.

`disable`

Plain TCP. If client requests TLS, it's ignored. Default.

`allow`

If client requests TLS, it is used. If not, plain TCP is used. If the client presents a client certificate, it is not validated.

`prefer`

Same as `allow`.

`require`

The client must use TLS. If not, the client connection is rejected. If the client presents a client certificate, it is not validated.

`verify-ca`

Client must use TLS with valid client certificate.

`verify-full`

Same as `verify-ca`.

`client_tls_key_file`

Private key for pgbouncer to accept client connections.

Default: not set

`client_tls_cert_file`

Certificate for private key. Clients can validate it.

Default: not set

`client_tls_ca_file`

Root certificate file to validate client certificates.

Default: not set

`client_tls_protocols`

Which TLS protocol versions are allowed. Allowed values: `tlsv1.0`, `tlsv1.1`, `tlsv1.2`, `tlsv1.3`. Shortcuts: `all` (`tlsv1.0,tlsv1.1,tlsv1.2,tlsv1.3`), `secure` (`tlsv1.2,tlsv1.3`), `legacy` (`all`).

Default: `secure`

`client_tls_ciphers`

Allowed TLS ciphers, in OpenSSL syntax. Shortcuts: `default/secure`, `compat/legacy`, `insecure/all`, `normal`, `fast`.

Only connections using TLS version 1.2 and lower are affected. There is currently no setting that controls the cipher choices used by TLS version 1.3 connections.

Default: `fast`

`client_tls_ecdhcurve`

Elliptic Curve name to use for ECDH key exchanges.

Allowed values: `none` (DH is disabled), `auto` (256-bit ECDH), curve name.

Default: `auto`

`client_tls_dheparams`

DHE key exchange type.

Allowed values: `none` (DH is disabled), `auto` (2048-bit DH), `legacy` (1024-bit DH).

Default: `auto`

`server_tls_sslmode`

TLS mode to use for connections to Postgres Pro servers. The default mode is `prefer`.

`disable`

Plain TCP. TLS is not even requested from the server.

`prefer`

TLS connection is always requested first from Postgres Pro. If refused, the connection will be established over plain TCP. Server certificate is not validated. Default.

`require`

Connection must go over TLS. If server rejects it, plain TCP is not attempted. Server certificate is not validated.

`verify-ca`

Connection must go over TLS and server certificate must be valid according to `server_tls_ca_file`. Server host name is not checked against certificate.

`verify-full`

Connection must go over TLS and server certificate must be valid according to `server_tls_ca_file`. Server host name must match certificate information.

`server_tls_ca_file`

Root certificate file to validate Postgres Pro server certificates.

Default: not set

`server_tls_key_file`

Private key for pgbouncer to authenticate against Postgres Pro server.

Default: not set

`server_tls_cert_file`

Certificate for private key. Postgres Pro server can validate it.

Default: not set

`server_tls_protocols`

Which TLS protocol versions are allowed. Allowed values: `tlsv1.0`, `tlsv1.1`, `tlsv1.2`, `tlsv1.3`. Shortcuts: `all` (`tlsv1.0,tlsv1.1,tlsv1.2,tlsv1.3`), `secure` (`tlsv1.2,tlsv1.3`), `legacy` (`all`).

Default: `secure`

`server_tls_ciphers`

Allowed TLS ciphers, in OpenSSL syntax. Shortcuts: `default/secure`, `compat/legacy`, `insecure/all`, `normal`, `fast`.

Only connections using TLS version 1.2 and lower are affected. There is currently no setting that controls the cipher choices used by TLS version 1.3 connections.

Default: `fast`

Dangerous Timeouts

Setting the following timeouts can cause unexpected errors.

`query_timeout`

Queries running longer than that are canceled. This should be used only with a slightly smaller server-side `statement_timeout`, to apply only for network problems. [seconds]

Default: 0.0 (disabled)

`query_wait_timeout`

Maximum time queries are allowed to spend waiting for execution. If the query is not assigned to a server during that time, the client is disconnected. The 0 value disables this parameter. If this is disabled, clients will be queued indefinitely. [seconds]

This setting is used to prevent unresponsive servers from grabbing up connections. It also helps when the server is down or rejects connections for any reason.

Default: 120.0

`cancel_wait_timeout`

Maximum time cancellation requests are allowed to spend waiting for execution. If the cancel request is not assigned to a server during that time, the client is disconnected. 0 disables. If this is disabled, cancel requests will be queued indefinitely. [seconds]

This setting is used to prevent a client locking up when a cancel cannot be forwarded due to the server being down.

Default: 10.0

`client_idle_timeout`

Client connections idling longer than this many seconds are closed. This should be larger than the client-side connection lifetime settings, and only used for network problems. [seconds]

Default: 0.0 (disabled)

`idle_transaction_timeout`

If a client has been in the “idle in transaction” state longer, it will be disconnected. [seconds]

Default: 0.0 (disabled)

`suspend_timeout`

How long to wait for buffer flush during `SUSPEND` or reboot (`-R`). A connection is dropped if the flush does not succeed. [seconds]

Default: 10

Low-Level Network Settings

`pkt_buf`

Internal buffer size for packets. Affects size of TCP packets sent and general memory usage. Actual libpq packets can be larger than this, so no need to set it large.

Default: 4096

`max_packet_size`

Maximum size for Postgres Pro packets that pgbouncer allows through. One packet is either one query or one result set row. The full result set can be larger.

Default: 2147483647

`listen_backlog`

The value of the `backlog` argument for `listen()`. Determines how many new unanswered connection attempts are kept in the queue. When the queue is full, further new connections are dropped.

Default: 128

`sbuf_loopcnt`

How many times to process data on one connection, before proceeding. Without this limit, one connection with a big result set can stall pgbouncer for a long time. One loop processes one `pkt_buf` amount of data. 0 means no limit.

Default: 5

`so_reuseport`

Specifies whether to set the socket option `SO_REUSEPORT` on TCP listening sockets. On some operating systems, this allows running multiple pgbouncer instances on the same host listening on the same port and having the kernel distribute the connections automatically. This option is a way to get pgbouncer to use more CPU cores. (pgbouncer is single-threaded and uses one CPU core per instance.)

This setting has the desired effect on Linux. On systems that don't support the socket option at all, turning this setting on will result in an error.

Each pgbouncer instance on the same host needs different settings for at least `unix_socket_dir` and `pidfile`, as well as `logfile` if that is used. Also note that if you make use of this option, you can no longer connect to a specific pgbouncer instance via TCP/IP, which might have implications for monitoring and metrics collection.

To make sure query cancellations keep working, you should set up pgbouncer peering between the different pgbouncer processes. For details see the [peer_id configuration option](#) and the [\[peers\] configuration section](#). There's also an example that uses peering and `so_reuseport` in the [Examples section](#).

Default: 0

`tcp_defer_accept`

Sets the `TCP_DEFER_ACCEPT` socket option; see `man 7 tcp` for details. (This is a Boolean option: 1 means enabled. The actual value set if enabled is currently hardcoded to 45 seconds.)

This is currently only supported on Linux.

Default: 1 on Linux, otherwise 0

`tcp_socket_buffer`

Default: not set

`tcp_keepalive`

Turns on basic keepalive with OS defaults.

On Linux, the system defaults are **`tcp_keepidle=7200`**, **`tcp_keepintvl=75`**, **`tcp_keepcnt=9`**. They are probably similar on other operating systems.

Default: 1

`tcp_keepcnt`

Default: not set

`tcp_keepidle`

Default: not set

`tcp_keepintvl`

Default: not set

`tcp_user_timeout`

Sets the `TCP_USER_TIMEOUT` socket option. This specifies the maximum amount of time in milliseconds that transmitted data may remain unacknowledged before the TCP connection is forcibly closed. If set to 0, then operating system's default is used.

This is currently only supported on Linux.

Default: 0

Section [databases]

The section `[databases]` defines the names of the databases that clients of pgbouncer can connect to and specifies where those connections will be routed. The section contains `key=value` lines like

```
dbname = connection string
```

where the key will be taken as a database name and the value as a connection string, consisting of `key=value` pairs of connection parameters, described below (similar to libpq, but the actual libpq is not used and the set of available features is different).

Example:

```
foodb = host=host1.example.com port=5432
```

```
bardb = host=localhost dbname=bazdb
```

The database name can contain characters `_0-9A-Za-z` without quoting. Names that contain other chars need to be quoted with standard SQL ident quoting: double quotes where `"` is taken as single quote.

The database name `pgbouncer` is reserved for the admin console and cannot be used as a key here.

* acts as fallback database: if the exact name does not exist, its value is taken as connection string for the requested database. For example, if there is the following entry (and no other overriding entries):

```
* = host=foo
```

In this case, a connection to `pgbouncer` specifying a database `bar` will effectively behave as if the following entry exists (taking advantage of the default for `dbname` being the client-side database name):

```
bar = host=foo dbname=bar
```

Such automatically created database entries are cleaned up if they stay idle longer than the time specified by the `autodb_idle_timeout` parameter.

`dbname`

Destination database name.

Default: same as client-side database name

`host`

Host name or IP address to connect to. Host names are resolved at connection time, the result is cached per `dns_max_ttl` parameter. When a host name's resolution changes, existing server connections are automatically closed when they are released (according to the pooling mode), and new server connections immediately use the new resolution. If DNS returns several results, they are used in a round-robin manner.

If the value begins with `/`, then a Unix socket in the file-system namespace is used. If the value begins with `@`, then a Unix socket in the abstract namespace is used.

A comma-separated list of host names or addresses can be specified. In that case, connections are made in a round-robin manner. (If a host list contains host names that in turn resolve via DNS to multiple addresses, the round-robin systems operate independently. This is an implementation dependency that is subject to change.) Note that in a list, all hosts must be available at all times: there are no mechanisms to skip unreachable hosts or to select only available hosts from a list or similar. (This is different from what a host list in `libpq` means.) Also note that this only affects how the destinations of new connections are chosen. See also the setting `server_round_robin` for how clients are assigned to already established server connections.

Examples:

```
host=localhost
host=127.0.0.1
host=2001:0db8:85a3:0000:0000:8a2e:0370:7334
host=/var/run/postgresql
host=192.168.0.1,192.168.0.2,192.168.0.3
```

Default: not set, meaning to use a Unix socket

`port`

Default: 5432

`user`

If `user=` is set, all connections to the destination database will be done with the specified user, meaning that there will be only one pool for this database.

Otherwise pgbouncer logs into the destination database with the client user name, meaning that there will be one pool per user.

password

If no password is specified here, the password from the `auth_file` or `auth_query` will be used.

auth_user

Override of the global `auth_user` setting, if specified.

pool_size

Set the maximum size of pools for this database. If not set, the `default_pool_size` is used.

min_pool_size

Set the minimum pool size for this database. If not set, the global `min_pool_size` is used.

reserve_pool

Set additional connections for this database. If not set, `reserve_pool_size` is used.

connect_query

Query to be executed after a connection is established, but before allowing the connection to be used by any clients. If the query raises errors, they are logged but ignored otherwise.

pool_mode

Set the pool mode specific to this database. If not set, the default `pool_mode` is used.

max_db_connections

Configure a database-wide maximum (i.e. all pools within the database will not have more than this many server connections).

client_encoding

Ask specific `client_encoding` from server.

datestyle

Ask specific `datestyle` from server.

timezone

Ask specific `timezone` from server.

Section [users]

This section contains `key=value` lines like

```
user1 = settings
```

where the key will be taken as a user name and the value as a list of configuration settings specific for this user.

Example:

```
user1 = pool_mode=session
```

Only a few settings are available here.

pool_mode

Set the pool mode to be used for all connections from this user. If not set, the database or default `pool_mode` is used.

`max_user_connections`

Configure a maximum for the user (i.e. all pools with the user will not have more than this many server connections).

Section [peers]

This section defines the peers that pgbouncer can forward cancellation requests to and where those cancellation requests will be routed.

pgbouncer processes can be peered together in a group by defining a `peer_id` value and a [peers] section in the configs of all the pgbouncer processes. These pgbouncer processes can then forward cancellation requests to the process that it originated from. This is needed to make cancellations work when multiple pgbouncer processes (possibly on different servers) are behind the same TCP load balancer. Cancellation requests are sent over different TCP connections than the query they are cancelling, so a TCP load balancer might send the cancellation request connection to a different process than the one that it was meant for. By peering them these cancellation requests eventually end up at the right process.

The section contains key=value lines like

```
peer_id = connection string
```

where the key will be taken as a `peer_id` and the value as a connection string, consisting of key=value pairs of connection parameters, described below (similar to libpq, but the actual libpq is not used and the set of available features is different).

Example:

```
1 = host=host1.example.com
2 = host=/tmp/pgbouncer-2 port=5555
```

Note

For peering to work, the `peer_id` of each pgbouncer process in the group must be unique within the peered group. And the [peers] section should contain entries for each of those peer IDs. An example can be found in the [Examples](#) section. It is allowed, but not necessary, for the [peers] section to contain the `peer_id` of the pgbouncer that the config is for. Such an entry will be ignored, but it is allowed to make config management easier. Because it allows using the exact same [peers] section for multiple configs.

`host`

Host name or IP address to connect to. Host names are resolved at connection time, the result is cached per `dns_max_ttl` parameter. If DNS returns several results, they are used in a round-robin manner. But in general it's not recommended to use a hostname that resolves to multiple IPs, because then the cancel request might still be forwarded to the wrong node and it would need to be forwarded again (which is only allowed up to three times).

If the value begins with `/`, then a Unix socket in the file-system namespace is used. If the value begins with `@`, then a Unix socket in the abstract namespace is used.

Examples:

```
host=localhost
host=127.0.0.1
host=2001:0db8:85a3:0000:0000:8a2e:0370:7334
host=/var/run/pgbouncer-1
```

`port`

Default: 6432

`pool_size`

If not set, the `default_pool_size` is used.

Include Directive

The pgbouncer configuration file can contain include directives, which specify another configuration file to read and process. This allows splitting the configuration file into physically separate parts. The include directives look like this:

```
%include filename
```

If the filename is not an absolute path, it is taken as relative to the current working directory.

Authentication File Format

This section describes the format of the file specified by the `auth_file` setting. It is a text file in the following format:

```
"username1" "password" ...
"username2" "md5abcdef012342345" ...
"username2" "SCRAM-SHA-256$iterations:salt$storedkey:serverkey"
```

There should be at least two fields, surrounded by double quotes. The first field is the user name and the second is either a plain-text, a MD5-hashed password, or a SCRAM secret. pgbouncer ignores the rest of the line. Double quotes in a field value can be escaped by writing two double quotes.

Postgres Pro MD5-hashed password format:

```
"md5" + md5(password + username)
```

```
So      user      admin      with      password      1234      will      have      MD5-hashed      password
md545f2603610af569b6155c45067268c6b.
```

Postgres Pro SCRAM secret format:

```
SCRAM-SHA-256$iterations:salt$storedkey:serverkey
```

The passwords or secrets stored in the authentication file serve two purposes. First, they are used to verify the passwords of incoming client connections, if a password-based authentication method is configured. Second, they are used as the passwords for outgoing connections to the backend server, if the backend server requires password-based authentication (unless the password is specified directly in the database's connection string). The latter works if the password is stored in plain text or MD5-hashed. SCRAM secrets can only be used for logging into a server if the client authentication also uses SCRAM, the pgbouncer database definition does not specify a user name, and the SCRAM secrets are identical in pgbouncer and the Postgres Pro server (same salt and iterations, not merely the same password). This is due to an inherent security property of SCRAM: the stored SCRAM secret cannot by itself be used for deriving login credentials.

The authentication file can be written by hand, but it's also useful to generate it from some other list of users and passwords. See `./etc/mkauth.py` for a sample script to generate the authentication file from the `pg_shadow` system table.

Alternatively, use `auth_query` instead of `auth_file` to avoid having to maintain a separate authentication file.

HBA File Format

The location of the HBA file is specified by the setting `auth_hba_file`. It is only used if `auth_type` is set to `hba`.

The file follows the format of the Postgres Pro `pg_hba.conf` file described in [Section 19.1](#).

- Supported record types: `local`, `host`, `hostssl`, `hostnossl`.

- **Database field:** Supports `all`, `sameuser`, `@file`, multiple names. Not supported: `replication`, `samerole`, `samegroup`.
- **User name field:** Supports `all`, `@file`, multiple names. Not supported: `+groupname`.
- **Address field:** Supports `IPv4`, `IPv6`. Not supported: DNS names, domain prefixes.
- **Auth-method field:** Only methods supported by `pgbouncer`'s `auth_type` are supported, plus `peer` and `reject`, but except `any` and `pam`, which only work globally. User name map (`map=`) parameter is not supported.

Examples

Small example configuration:

```
[databases]
template1 = host=localhost dbname=template1 auth_user=someuser

[pgbouncer]
pool_mode = session
listen_port = 6432
listen_addr = localhost
auth_type = md5
auth_file = users.txt
logfile = pgbouncer.log
pidfile = pgbouncer.pid
admin_users = someuser
stats_users = stat_collector
```

Database examples:

```
[databases]

; foodb over Unix socket
foodb =

; redirect bardb to bazdb on localhost
bardb = host=localhost dbname=bazdb

; access to destination database will go with single user
forcedb = host=localhost port=300 user=baz password=foo client_encoding=UNICODE
datestyle=ISO
```

Example of a secure function for `auth_query`:

```
CREATE OR REPLACE FUNCTION pgbouncer.user_lookup(in i_username text, out uname text,
out phash text)
RETURNS record AS $$
BEGIN
    SELECT username, passwd FROM pg_catalog.pg_shadow
    WHERE username = i_username INTO uname, phash;
    RETURN;
END; $$ LANGUAGE plpgsql SECURITY DEFINER;
REVOKE ALL ON FUNCTION pgbouncer.user_lookup(text) FROM public, pgbouncer;
GRANT EXECUTE ON FUNCTION pgbouncer.user_lookup(text) TO pgbouncer;
```

Example configs for 2 peered `pgbouncer` processes to create a multi-core `pgbouncer` setup using [so_reuseport](#).

The config for the first process:

```
[databases]
postgres = host=localhost dbname=postgres
```

```
[peers]
1 = host=/tmp/pgbouncer1
2 = host=/tmp/pgbouncer2

[pgbouncer]
listen_addr=127.0.0.1
auth_file=auth_file.conf
so_reuseport=1
unix_socket_dir=/tmp/pgbouncer1
peer_id=1
```

The config for the second process:

```
[databases]
postgres = host=localhost dbname=postgres

[peers]
1 = host=/tmp/pgbouncer1
2 = host=/tmp/pgbouncer2

[pgbouncer]
listen_addr=127.0.0.1
auth_file=auth_file.conf
so_reuseport=1
; only unix_socket_dir and peer_id are different
unix_socket_dir=/tmp/pgbouncer2
peer_id=2
```

pg_filedump

`pg_filedump` — display formatted contents of a Postgres Pro heap, index, or control file

Synopsis

```
pg_filedump [option...] [file]
```

Description

`pg_filedump` is a utility to format Postgres Pro heap/index/control files into a human-readable form. You can format/dump the files several ways, as listed in the [Options](#) section, as well as dump a straight binary. The type of file (heap/index) can usually be determined automatically by the content of the blocks within the file. However, to format a `pg_control` file you must use the `-c` option. The default is to format the entire file using the block size listed in block 0 and display block relative addresses. These defaults can be modified using run-time options. Some options may seem strange but they are there for a reason. For example, block size. It is there because if the header of block 0 is corrupt, you need a method of forcing a block size.

Installation

`pg_filedump` is provided with Postgres Pro Standard as a separate pre-built package `pg-file-dump-std-16` (for the detailed installation instructions, see [Chapter 16](#)).

Options

Defaults are: relative addressing, range of the entire file, block size as listed on block 0 in the file.

The following options are valid for heap and index files:

- `-a`
Display absolute addresses when formatting. Block header information is always block-relative.
- `-b`
Display binary block images within a range. The option will turn off all formatting options.
- `-d`
Display formatted block content dump. The option will turn off all other formatting options.
- `-D attrlist`
Decode tuples using given comma-separated list of types. The list of supported types:

```
bigint  
bigserial  
bool  
char  
charN — char(n)  
date  
float  
float4  
float8  
int  
json  
macaddr  
name  
numeric  
oid  
real
```

```

serial
smallint
smallserial
text
time
timestamp
timetz
uuid
varchar
varcharN — varchar(n)
xid
xml
~ — ignore all attributes left in a tuple

```

- f
Display formatted block content dump along with interpretation.
- h
Display help.
- i
Display interpreted item details.
- k
Verify block checksums.
- o
Do not dump old values.
- R *startblock* [*endblock*]
Display specific block ranges within the file. Blocks are indexed from 0. *startblock*: block to start at. *endblock*: block to end at. A *startblock* without an *endblock* will format a single block.
- s *segsize*
Force segment size to *segsize*.
- t
Dump TOAST files.
- v
Output additional information about TOAST relations.
- n *segnumber*
Force segment number to *segnumber*.
- S *blocksize*
Force block size to *blocksize*.
- x
Force interpreted formatting of block items as index items.
- y
Force interpreted formatting of block items as heap items.

The following options are valid for control files:

`-c`

Interpret the file listed as a control file.

`-f`

Display formatted content dump along with interpretation.

`-S blocksize`

Force block size to *blocksize*.

Additional parameters:

`-m`

Interpret file as `pg_filenode.map` file and print contents. All other options will be ignored.

In most cases, it is recommended to use the `-i` and `-f` options to get the most useful dump output.

Appendix J. External Projects

Postgres Pro is a complex software project, and managing the project is difficult. We have found that many enhancements to Postgres Pro can be more efficiently developed separately from the core project.

J.1. Client Interfaces

There are only two client interfaces included in the base Postgres Pro Standard distribution:

- [libpq](#) is included because it is the primary C language interface, and because many other client interfaces are built on top of it.
- [ECPG](#) is included because it depends on the server-side SQL grammar, and is therefore sensitive to changes in Postgres Pro itself.

All other language interfaces are external projects and are distributed separately. A [list of language interfaces](#) is maintained on the PostgreSQL wiki. Note that some of these packages are not released under the same license as Postgres Pro. For more information on each language interface, including licensing terms, refer to its website and documentation.

https://wiki.postgresql.org/wiki/List_of_drivers

J.2. Administration Tools

There are several administration tools available for Postgres Pro. One of them is [Postgres Pro Enterprise Manager](#), an integrated administration panel for Postgres Pro management. It provides centralized privilege-based access to a unified management and monitoring interface with embedded command line. There are other solutions, e.g. an open-source platform [pgAdmin](#).

J.3. Procedural Languages

Postgres Pro includes several procedural languages with the base distribution: [PL/pgSQL](#), [PL/Tcl](#), [PL/Perl](#), and [PL/Python](#).

In addition, there are a number of procedural languages that are developed and maintained outside the core Postgres Pro distribution. A list of [procedural languages](#) is maintained on the PostgreSQL wiki. Note that some of these projects are not released under the same license as Postgres Pro. For more information on each procedural language, including licensing information, refer to its website and documentation.

https://wiki.postgresql.org/wiki/PL_Matrix

J.4. Extensions

Postgres Pro is designed to be easily extensible. For this reason, extensions loaded into the database can function just like features that are built in. The extensions shipped with Postgres Pro are described in [Appendix F](#). Other extensions are developed independently, like [PostGIS](#). Even Postgres Pro replication solutions can be developed externally. For example, [Slony-I](#) is a popular primary/standby replication solution that is developed independently from the core project.

Appendix K. Configuring Postgres Pro for 1C Solutions

This section describes how to configure Postgres Pro for work with 1C solutions to get the maximum performance and stability.

K.1. Configuring the Locale

Before configuring Postgres Pro for 1C solutions, make sure that the Russian locale is installed on the system and that it is the active locale of the user who creates the database cluster. The following example shows how to set up the `ru_RU.UTF-8` locale for Debian systems:

```
sudo dpkg-reconfigure locales
export LANG="ru_RU.UTF-8"
/opt/pgpro/std-16/bin/pg-setup initdb
```

For more details, see related documentation sections for your operating system and for 1C.

K.2. Basic Server Requirements and Configuration

To provide high performance for 1C solutions, the Postgres Pro server must have at least the following hardware characteristics:

- 8 - 512 GB of RAM
- 4 - 256 CPU cores
- RAID 0-1 or SSD

The exact recommended characteristics depend on your system's specifics and the load on it.

It is recommended to configure the Postgres Pro server as follows:

- Disable the hyper-threading technology.
- Disable energy saving. Otherwise, delays of database responses may increase unpredictably.
- Disable swapping for POSIX/System V shared memory.

K.3. Configuring Server Parameters

This document describes how to specify configuration parameters of the Postgres Pro server for the maximum performance and stability when working with 1C solutions. Edit these parameters in the `postgresql.conf` configuration file. Note that all given parameter values are approximate. They can be considered as a starting point for further fine-tuning.

For fast automatic tuning of Postgres Pro, you can also use the [pgpro_tune](#) utility. It provides the `1c.tune` preset that specifies optimal values for 1C-specific configuration parameters. For detailed information about the usage of this utility, see [its documentation](#).

K.3.1. Connection Parameters

Increase the maximum number of allowed concurrent connections to the database server using the [max_connections](#) configuration parameter. 1C solutions can open a large number of connections even if not all of them are used. Therefore, it is recommended to allow not less than 500 connections. The higher the number of client sessions, the higher the parameter value should be.

```
-- max_connections = 500..10000
```

K.3.2. Memory Consumption Parameters

1. Increase the amount of memory allocated by the database for data caching. To do this, use the [shared_buffers](#) configuration parameter. For good performance, it is recommended to set this parameter to at least 25% of the available system RAM.

```
-- shared_buffers = RAM/4
```

2. Increase the maximum amount of memory used for temporary buffers within each database session to ensure that all temporary tables are handled correctly. To do this, use the [temp_buffers](#) configuration parameter.

The recommended value should be between 32MB and 256MB. The exact value depends on the amount of memory on the server and the number of concurrent connections. The more connections and the smaller the amount of memory, the smaller the parameter value should be.

```
-- temp_buffers = 32..256MB
```

3. Increase the maximum amount of memory to be used by a single query operation before writing to temporary disk files. To do this, use the [work_mem](#) configuration parameter.

When choosing the parameter value, note that a complex query might perform several sort and hash operations at the same time, and each of them can use the specified amount of memory. Also, several running sessions can perform such operations concurrently. Therefore, the total used memory can be many times greater than the specified value. You can fine-tune the parameter value by monitoring the number of temporary files created in the system.

```
-- work_mem = RAM/32..64 or 32MB..256MB
```

4. Increase the maximum amount of memory to be used by maintenance database operations, such as `VACUUM` or `CREATE INDEX`. To do this, use the [maintenance_work_mem](#) configuration parameter.

Note that only one of these operations can be executed at a time by a database session. Therefore, you can set this value significantly larger than `work_mem`. Larger values can improve performance for vacuuming and restoring database dumps.

```
-- maintenance_work_mem = RAM/16..32 or work_mem * 4 or 256MB..4GB
```

5. In the case of significant memory fragmentation, specify the following environment variable in the `/etc/systemd/system/postgresql.service` file:

```
-- Environment = MALLOC_MMAP_THRESHOLD_= 8192
```

K.3.3. Kernel Resource Usage Parameters

Increase the maximum number of simultaneously open files allowed to each server subprocess. To do this, use the [max_files_per_process](#) configuration parameter.

The recommended value is 10000 but it can be increased depending on the load. The maximum allowed value depends on the operating system. If the server reaches the specified limit, it starts to open and close files, which affects the performance. You can monitor open files using the `lsof` command.

```
-- max_files_per_process = 10000
```

K.3.4. Background Writer Parameters

1. Decrease the delay between activity rounds for the background writer using the [bgwriter_delay](#) configuration parameter. Note that a too high parameter value will increase the load on the checkpoint process and the backend processes, while a too low value will result in the full load of one of the cores.

```
-- bgwriter_delay = 20ms
```

2. Increase values for the [bgwriter_lru_multiplier](#) and [bgwriter_lru_maxpages](#) configuration parameters that control the number of dirty buffers written by the background writer in each round.

```
-- bgwriter_lru_multiplier = 4.0
-- bgwriter_lru_maxpages = 400
```

K.3.5. Asynchronous Behavior Parameters

1. Specify the number of concurrent disk I/O operations that any individual Postgres Pro session attempts to initiate in parallel. To do this, use the [effective_io_concurrency](#) configuration parameter. Currently, this parameter affects bitmap heap scans only.

For magnetic drives, a good starting point for this parameter is the number of separate drives comprising a RAID 0 stripe or RAID 1 mirror used for the database. However, too high parameter values will keep the disk array busy, which results in extra CPU overhead.

SSD disks can often process many concurrent requests, so the best value might be in the hundreds.

```
-- effective_io_concurrency = 2
```

2. Set the [max_parallel_workers_per_gather](#) configuration parameter to 0. This disables parallel queries that can be started by `Gather` and `Gather Merge` nodes. Parallel queries may consume very significantly more resources than non-parallel queries.

```
-- max_parallel_workers_per_gather = 0
```

K.3.6. WAL Parameters

1. Leave the [fsync](#) configuration parameter set to `on` (default). In this case, the Postgres Pro server tries to make sure that updates are physically written to disk by issuing the `fsync()` system calls. This ensures that the database cluster can recover to a consistent state after an operating system or hardware crash.

Although disabling the `fsync` parameter often leads to a performance benefit, this can result in unrecoverable data corruption in case of a power failure or system crash.

```
-- fsync = on
```

Important note: if your RAID has a cache and works in the write-back mode, make sure that the disk controller cache has a valid battery. Otherwise, data written to the cache will be lost in the case of a power failure, and the Postgres Pro server will be unable to recover the data.

2. Set the [synchronous_commit](#) configuration parameter to `off`. This means that the Postgres Pro server does not wait for writing WAL records to disk but returns a success indication to the client.

Unlike [fsync](#), setting this parameter to `off` does not create any risk of database inconsistency. An operating system or database crash might only result in some recent transactions being lost. Thus, disabling the `synchronous_commit` parameter is useful when high performance is very important.

```
-- synchronous_commit = off
```

3. Increase values for the [checkpoint_timeout](#), [min_wal_size](#), and [max_wal_size](#) configuration parameters to reduce the frequency of checkpoints. Too frequent checkpoints lead to the significant load on the disk system.

```
-- checkpoint_timeout = 15min
-- min_wal_size = 512MB..4G
-- max_wal_size = 2 * min_wal_size
```

4. Specify the [commit_delay](#) configuration parameter if the average number of transactions per second (TPS) exceeds 1000. This parameter adds a time delay before a WAL flush is initiated and can improve the group commit throughput.

```
-- commit_delay = 1000
```

K.3.7. Query Planning Parameters

1. Specify the [effective_cache_size](#) configuration parameter to define the planner's assumption about the effective size of the disk cache that is available to a single query.

The query optimizer's performance depends on the amount of allocated RAM. A higher value makes it more likely index scans will be used, while a lower value results in using sequential scans.

```
-- effective_cache_size = RAM - shared_buffers
```

2. Specify the [random_page_cost](#) configuration parameter to define the planner's estimate of the cost of a non-sequentially-fetched disk page.

The parameter value is specified relative to the [seq_page_cost](#) parameter, which is set to 1.0 by default. Reducing the [random_page_cost](#) value will cause the system to prefer index scans to sequential scans. The recommended value depends on the seek time of the disk system. The smaller the seek time, the smaller the parameter value should be (but not less than 1.0).

```
-- random_page_cost = 1.5-2.0 (for RAID) or 1.1-1.3 (for SSD)
```

3. Increase the value for the [from_collapse_limit](#) configuration parameter. The planner will merge sub-queries into upper queries if the resulting FROM list would have no more than this many items. Note that smaller parameter values reduce planning time but can lead to less efficient query plans.

```
-- from_collapse_limit = 20
```

4. Increase the value of the [join_collapse_limit](#) configuration parameter. The planner will rewrite explicit JOIN constructs (except FULL JOINS) into lists of FROM items whenever a list contains no more than this many items. Note that smaller parameter values reduce planning time but can lead to less efficient query plans.

```
-- join_collapse_limit = 20
```

5. Leave the [geqo](#) configuration parameter set to on (default). This enables the genetic query optimizer (GEQO) that does query planning using the heuristic search. GEQO reduces planning time for complex queries joining many relations but sometimes may produce plans that are less efficient than plans chosen by the regular exhaustive-search algorithm.

To manage the use of GEQO, specify the [geqo_threshold](#) configuration parameter. GEQO will be used to plan queries that involve at least the specified number of FROM items.

```
-- geqo = on
-- geqo_threshold = 12
```

6. Set the [jit](#) configuration parameter to off to disable Just-in-Time (JIT) compilation. This compilation is beneficial primarily for long-running CPU-bound queries, such as analytical queries. For short queries, the added overhead will be higher than the time that JIT compilation can save.

```
-- jit = off
```

K.3.8. Automatic Vacuuming Parameters

1. Leave the [autovacuum](#) configuration parameter set to on (default) to run the autovacuum launcher daemon. Note that disabling the autovacuum launcher daemon will lead to increasing the database size and significant performance degradation.

```
-- autovacuum = on
```

2. Increase the maximum number of autovacuum processes that may be running at the same time using the [autovacuum_max_workers](#) configuration parameter. The more write requests are executed in the system, the more autovacuum processes are required.

```
-- autovacuum_max_workers = CPU cores/4..2 (but no less than 4)
```

3. Decrease the minimum delay between autovacuum rounds using the `autovacuum_naptime` configuration parameter. If a parameter value is too high, there can be not enough time to clean the required tables. This will lead to increasing the database size and significant performance degradation. However, a too low parameter value leads to the useless load.

```
-- autovacuum_naptime = 20s
```

K.3.9. Client Connection Parameters

1. Specify the directory in which to create temporary tables and indexes on temporary tables using the `temp_tablespaces` configuration parameter. Typically, 1C solutions use a lot of temporary tables. To increase the performance when working with these tables, locate this directory on separate fast disks.

Before this, you should first create the tablespace using the `CREATE TABLESPACE` command. If characteristics of the target disks differ from the main disks, specify the corresponding value for the `random_page_cost` parameter in this command.

```
-- temp_tablespaces = 'tablespace_name'
```

2. Set the `row_security` configuration parameter to `off` to raise an error if a query's results are filtered by a `row-level security` policy.

```
-- row_security = off
```

K.3.10. Lock Management Parameters

Increase the value for the `max_locks_per_transaction` configuration parameter up to 256. It specifies how many objects per server process or prepared transaction can be locked at the same time.

Typically, 1C solutions use a lot of temporary tables. Every backend process usually contains multiple temporary tables. When closing a connection, Postgres Pro tries to drop all temporary tables in a single transaction, so this transaction may use a lot of locks. If the number of locks exceeds the `max_locks_per_transaction` value, the transaction will fail leaving multiple orphaned temporary tables.

```
-- max_locks_per_transaction = 256
```

K.3.11. Parameters for 1C Compatibility

1. Set the `standard_conforming_strings` configuration parameter to `off` to enable backslash escapes (`\`) in all strings.

```
-- standard_conforming_strings = off
```

2. Set the `escape_string_warning` configuration parameter to `off` to switch off the warning about using the backslash escape symbol.

```
-- escape_string_warning = off
```

K.3.12. Path to `pg_stat_tmp` Subdirectory

Change the default path to the `PGDATA/pg_stat_tmp` subdirectory to locate it separately from the cluster directory. This subdirectory contains temporary files for the statistics subsystem. These files are changed intensively, which creates the significant load on the disk system. It is recommended to locate this subdirectory in `tmpfs` (temporary file storage).

K.4. Additional Modules

K.4.1. Built-In Default Modules

To provide support for 1C solutions, the Postgres Pro distribution includes the following built-in modules that are enabled by default and do not require additional configuration:

- [fasttrun](#) — provides a transaction-unsafe function to truncate temporary tables without growing the size of `pg_class`.
- [fulleq](#) — provides an additional equivalence operator for compatibility with Microsoft SQL Server.
- [mchar](#) — provides additional `MCHAR` and `MVARCHAR` data types for compatibility with Microsoft SQL Server.

K.4.2. `dbcopies_decoding`

`dbcopies_decoding` is a 1C module for updating database copies, which is enabled by default. To use the logical replication mechanism of this module, set the `wal_level` parameter to `logical`.

For more information about this module, contact 1C support.

K.4.3. `plantuner`

The `plantuner` module allows optimizing query execution plans. To configure it for 1C solutions, do the following:

1. Add the library name to the `shared_preload_libraries` variable in the `postgresql.conf` file.

```
shared_preload_libraries = 'plantuner'
```

2. Set the `plantuner.fix_empty_table` parameter to `on` to improve planning for recently created empty tables.

```
plantuner.fix_empty_table = on
```

K.4.4. `online_analyze`

The `online_analyze` module provides a set of features that immediately update statistics after `INSERT`, `UPDATE`, `DELETE`, `SELECT INTO`, or `COPY` operations for the affected tables.

To configure this module, follow the steps below.

1. Add the library name to the `shared_preload_libraries` variable in the `postgresql.conf` file.

```
shared_preload_libraries = 'online_analyze'
```

2. Enable this module.

```
online_analyze.enable = on
```

3. Specify the minimum number of row updates before starting online analysis.

```
online_analyze.threshold = 50
```

4. Specify the fraction of the table size to start online analysis.

```
online_analyze.scale_factor = 0.1
```

5. Execute the `ANALYZE` command without `VERBOSE`.

```
online_analyze.verbose = off
```

6. Enable online analysis for temporary tables.

```
online_analyze.table_type = 'temporary'
```

7. Specify the minimum time interval between `ANALYZE` calls per table, in milliseconds.

```
online_analyze.min_interval = 10000
```

Appendix L. Postgres Pro Limits

[Table L.1](#) describes various hard limits of Postgres Pro. However, practical limits, such as performance limitations or available disk space may apply before absolute hard limits are reached.

Table L.1. Postgres Pro Limitations

Item	Upper Limit	Comment
database size	unlimited	
number of databases	4,294,950,911	
relations per database	1,431,650,303	
relation size	32 TB	with the default <code>BLCKSZ</code> of 8192 bytes
rows per table	limited by the number of tuples that can fit onto 4,294,967,295 pages	
columns per table	1,600	further limited by tuple size fitting on a single page; see note below
columns in a result set	1,664	
field size	1 GB	
indexes per table	unlimited	constrained by maximum relations per database
columns per index	32	can be increased by recompiling Postgres Pro
partition keys	32	can be increased by recompiling Postgres Pro
identifier length	63 bytes	can be increased by recompiling Postgres Pro
function arguments	100	can be increased by recompiling Postgres Pro
query parameters	65,535	

The maximum number of columns for a table is further reduced as the tuple being stored must fit in a single 8192-byte heap page. For example, excluding the tuple header, a tuple made up of 1,600 `int` columns would consume 6400 bytes and could be stored in a heap page, but a tuple of 1,600 `bigint` columns would consume 12800 bytes and would therefore not fit inside a heap page. Variable-length fields of types such as `text`, `varchar`, and `char` can have their values stored out of line in the table's TOAST table when the values are large enough to require it. Only an 18-byte pointer must remain inside the tuple in the table's heap. For shorter length variable-length fields, either a 4-byte or 1-byte field header is used and the value is stored inside the heap tuple.

Columns that have been dropped from the table also contribute to the maximum column limit. Moreover, although the dropped column values for newly created tuples are internally marked as null in the tuple's null bitmap, the null bitmap also occupies space.

Each table can store a theoretical maximum of 2^{32} out-of-line values; see [Section 70.2](#) for a detailed discussion of out-of-line storage. This limit arises from the use of a 32-bit OID to identify each such value. The practical limit is significantly less than the theoretical limit, because as the OID space fills up, finding an OID that is still free can become expensive, in turn slowing down INSERT/UPDATE statements. Typically, this is only an issue for tables containing many terabytes of data; partitioning is a possible workaround.

Appendix M. Demo Database

“Airlines”

This is an overview of a demo database for Postgres Pro. This appendix describes the database schema, which consists of eight tables and several views. The subject field of this database is airline flights in Russia. You can download the database from [our website](#). See [Section M.1](#) for details.

Figure M.1. Airlines in Russia

You can use this database for various purposes, such as:

- learning SQL language on your own
- preparing books, manuals, and courses on SQL
- showing Postgres Pro features in stories and articles

When developing this demo database, we pursued several goals:

- Database schema must be simple enough to be understood without extra explanations.
- At the same time, database schema must be complex enough to allow writing meaningful queries.
- The database must contain true-to-life data that will be interesting to work with.

This demo database is distributed under the [PostgreSQL license](#).

You can send us your feedback to edu@postgrespro.ru.

M.1. Installation

The demo database is available at edu.postgrespro.com in three flavors, which differ only in the data size:

- [demo-small-en.zip](#) (21 MB) — flight data for one month (DB size is about 300 MB)
- [demo-medium-en.zip](#) (62 MB) — flight data for three months (DB size is about 700 MB)
- [demo-big-en.zip](#) (232 MB) — flight data for one year (DB size is about 2.5 GB)

The small database is good for writing queries, and it will not take up much disk space. The large database can help you understand the query behavior on large data volumes and consider query optimization.

The files include an SQL script that creates the `demo` database and fills it with data (virtually, it is a backup copy created with the `pg_dump` utility). The owner of the `demo` database will be the DBMS user who runs the script. For example, to create the small database, run the script as the user `postgres` by means of `psql`:

```
psql -f demo_small_YYYYMMDD.sql -U postgres
```

Note that if the `demo` database already exists, it will be deleted and recreated!

M.2. Schema Diagram

Figure M.2. Bookings Schema Diagram

M.3. Schema Description

The main entity is a booking (`bookings`).

One booking can include several passengers, with a separate ticket (`tickets`) issued to each passenger. A ticket has a unique number and includes information about the passenger. As such, the passenger is not a separate entity. Both the passenger's name and identity document number can change over time, so it is impossible to uniquely identify all the tickets of a particular person; for simplicity, we can assume that all passengers are unique.

The ticket includes one or more flight segments (`ticket_flights`). Several flight segments can be included into a single ticket if there are no non-stop flights between the points of departure and destination (connecting flights), or if it is a round-trip ticket. Although there is no constraint in the schema, it is assumed that all tickets in the booking have the same flight segments.

Each flight (`flights`) goes from one airport (`airports`) to another. Flights with the same flight number have the same points of departure and destination, but differ in departure date.

At flight check-in, the passenger is issued a boarding pass (`boarding_passes`), where the seat number is specified. The passenger can check in for the flight only if this flight is included into the ticket. The flight-seat combination must be unique to avoid issuing two boarding passes for the same seat.

The number of seats (`seats`) in the aircraft and their distribution between different travel classes depends on the model of the aircraft (`aircrafts`) performing the flight. It is assumed that every aircraft model has only one cabin configuration. Database schema does not check that seat numbers in boarding passes have the corresponding seats in the aircraft (such verification can be done using table triggers, or at the application level).

M.4. Schema Objects

M.4.1. List of Relations

Name	Type	Small	Medium	Big	Description
<code>aircrafts</code>	view				Aircraft
<code>aircrafts_data</code>	table	16 kB	16 kB	16 kB	Aircraft (translations)
<code>airports</code>	view				Airports
<code>airports_data</code>	table	56 kB	56 kB	56 kB	Airports (translations)
<code>boarding_passes</code>	table	31 MB	102 MB	427 MB	Boarding passes
<code>bookings</code>	table	13 MB	30 MB	105 MB	Bookings
<code>flights</code>	table	3 MB	6 MB	19 MB	Flights
<code>flights_v</code>	view				Flights
<code>routes</code>	view				Routes
<code>seats</code>	table	88 kB	88 kB	88 kB	Seats
<code>ticket_flights</code>	table	64 MB	145 MB	516 MB	Flight segments
<code>tickets</code>	table	47 MB	107 MB	381 MB	Tickets

M.4.2. View `bookings.aircrafts`

Each aircraft model is identified by its three-digit code (`aircraft_code`). The view also includes the name of the aircraft model (`model`) and the maximal flying distance, in kilometers (`range`).

The value of the `model` field is selected according to the chosen language. See [Section M.4.15](#) for details.

Column	Type	Modifiers	Description
<code>aircraft_code</code>	<code>char(3)</code>	<code>not null</code>	Aircraft code, IATA
<code>model</code>	<code>text</code>	<code>not null</code>	Aircraft model
<code>range</code>	<code>integer</code>	<code>not null</code>	Maximal flying distance, km

View definition:

```
SELECT ml.aircraft_code,
       ml.model ->> lang() AS model,
       ml.range
FROM   aircrafts_data ml;
```

M.4.3. Table `bookings.aircrafts_data`

This is the base table for the `aircrafts` view. The `model` field of this table contains translations of aircraft models to different languages, in the JSONB format. In most cases, this table is not supposed to be used directly.

Column	Type	Modifiers	Description
<code>aircraft_code</code>	<code>char(3)</code>	<code>not null</code>	Aircraft code, IATA

```

model          | jsonb   | not null   | Aircraft model
range          | integer | not null   | Maximal flying distance, km

```

Indexes:

```
PRIMARY KEY, btree (aircraft_code)
```

Check constraints:

```
CHECK (range > 0)
```

Referenced by:

```

TABLE "flights" FOREIGN KEY (aircraft_code)
REFERENCES aircrafts_data(aircraft_code)
TABLE "seats" FOREIGN KEY (aircraft_code)
REFERENCES aircrafts_data(aircraft_code) ON DELETE CASCADE

```

M.4.4. View bookings.airports

An airport is identified by a three-letter code (`airport_code`) and has a name (`airport_name`).

There is no separate entity for the city, but there is a city name (`city`) to identify the airports of the same city. The view also includes coordinates (`coordinates`) and the time zone (`timezone`).

The values of the `airport_name` and `city` fields are selected according to the chosen language. See [Section M.4.15](#) for details.

Column	Type	Modifiers	Description
<code>airport_code</code>	<code>char(3)</code>	<code>not null</code>	Airport code
<code>airport_name</code>	<code>text</code>	<code>not null</code>	Airport name
<code>city</code>	<code>text</code>	<code>not null</code>	City
<code>coordinates</code>	<code>point</code>	<code>not null</code>	Airport coordinates (longitude and latitude)
<code>timezone</code>	<code>text</code>	<code>not null</code>	Airport time zone

View definition:

```

SELECT ml.airport_code,
       ml.airport_name ->> lang() AS airport_name,
       ml.city ->> lang() AS city,
       ml.coordinates,
       ml.timezone
FROM airports_data ml;

```

M.4.5. Table bookings.airports_data

This is the base table for the `airports` view. This table contains translations of `airport_name` and `city` values to different languages, in the JSONB format. In most cases, this table is not supposed to be used directly.

Column	Type	Modifiers	Description
<code>airport_code</code>	<code>char(3)</code>	<code>not null</code>	Airport code
<code>airport_name</code>	<code>jsonb</code>	<code>not null</code>	Airport name
<code>city</code>	<code>jsonb</code>	<code>not null</code>	City
<code>coordinates</code>	<code>point</code>	<code>not null</code>	Airport coordinates (longitude and latitude)
<code>timezone</code>	<code>text</code>	<code>not null</code>	Airport time zone

Indexes:

```
PRIMARY KEY, btree (airport_code)
```

Referenced by:

```

TABLE "flights" FOREIGN KEY (arrival_airport)
REFERENCES airports_data(airport_code)
TABLE "flights" FOREIGN KEY (departure_airport)
REFERENCES airports_data(airport_code)

```

M.4.6. Table `bookings.boarding_passes`

At the time of check-in, which opens twenty-four hours before the scheduled departure, the passenger is issued a boarding pass. Like the flight segment, the boarding pass is identified by the ticket number and the flight number.

Boarding passes are assigned sequential numbers (`boarding_no`), in the order of check-ins for the flight (this number is unique only within the context of a particular flight). The boarding pass specifies the seat number (`seat_no`).

Column	Type	Modifiers	Description
<code>ticket_no</code>	<code>char(13)</code>	<code>not null</code>	Ticket number
<code>flight_id</code>	<code>integer</code>	<code>not null</code>	Flight ID
<code>boarding_no</code>	<code>integer</code>	<code>not null</code>	Boarding pass number
<code>seat_no</code>	<code>varchar(4)</code>	<code>not null</code>	Seat number

Indexes:

```
PRIMARY KEY, btree (ticket_no, flight_id)
UNIQUE CONSTRAINT, btree (flight_id, boarding_no)
UNIQUE CONSTRAINT, btree (flight_id, seat_no)
```

Foreign-key constraints:

```
FOREIGN KEY (ticket_no, flight_id)
REFERENCES ticket_flights(ticket_no, flight_id)
```

M.4.7. Table `bookings.bookings`

Passengers book tickets for themselves, and, possibly, for several other passengers, in advance (`book_date`, not earlier than one month before the flight). The booking is identified by its number (`book_ref`, a six-position combination of letters and digits).

The `total_amount` field stores the total cost of all tickets included into the booking, for all passengers.

Column	Type	Modifiers	Description
<code>book_ref</code>	<code>char(6)</code>	<code>not null</code>	Booking number
<code>book_date</code>	<code>timestampz</code>	<code>not null</code>	Booking date
<code>total_amount</code>	<code>numeric(10,2)</code>	<code>not null</code>	Total booking cost

Indexes:

```
PRIMARY KEY, btree (book_ref)
```

Referenced by:

```
TABLE "tickets" FOREIGN KEY (book_ref) REFERENCES bookings(book_ref)
```

M.4.8. Table `bookings.flights`

The natural key of the `bookings.flights` table consists of two fields — `flight_no` and `scheduled_departure`. To make foreign keys for this table more compact, a surrogate key is used as the primary key (`flight_id`).

A flight always connects two points — the airport of departure (`departure_airport`) and arrival (`arrival_airport`). There is no such entity as a “connecting flight”: if there are no non-stop flights from one airport to another, the ticket simply includes several required flight segments.

Each flight has a scheduled date and time of departure (`scheduled_departure`) and arrival (`scheduled_arrival`). The actual departure time (`actual_departure`) and arrival time (`actual_arrival`) can differ: the difference is usually not very big, but sometimes can be up to several hours if the flight is delayed.

Flight status (*status*) can take one of the following values:

Scheduled

The flight is available for booking. It happens one month before the planned departure date; before that time, there is no entry for this flight in the database.

On Time

The flight is open for check-in (in twenty-four hours before the scheduled departure) and is not delayed.

Delayed

The flight is open for check-in (in twenty-four hours before the scheduled departure) but is delayed.

Departed

The aircraft has already departed and is airborne.

Arrived

The aircraft has reached the point of destination.

Cancelled

The flight is canceled.

Column	Type	Modifiers	Description
flight_id	serial	not null	Flight ID
flight_no	char(6)	not null	Flight number
scheduled_departure	timestampz	not null	Scheduled departure time
scheduled_arrival	timestampz	not null	Scheduled arrival time
departure_airport	char(3)	not null	Airport of departure
arrival_airport	char(3)	not null	Airport of arrival
status	varchar(20)	not null	Flight status
aircraft_code	char(3)	not null	Aircraft code, IATA
actual_departure	timestampz		Actual departure time
actual_arrival	timestampz		Actual arrival time

Indexes:

PRIMARY KEY, btree (flight_id)
 UNIQUE CONSTRAINT, btree (flight_no, scheduled_departure)

Check constraints:

CHECK (scheduled_arrival > scheduled_departure)
 CHECK ((actual_arrival IS NULL)
 OR ((actual_departure IS NOT NULL AND actual_arrival IS NOT NULL)
 AND (actual_arrival > actual_departure)))
 CHECK (status IN ('On Time', 'Delayed', 'Departed',
 'Arrived', 'Scheduled', 'Cancelled'))

Foreign-key constraints:

FOREIGN KEY (aircraft_code)
 REFERENCES aircrafts(aircraft_code)
 FOREIGN KEY (arrival_airport)
 REFERENCES airports(airport_code)
 FOREIGN KEY (departure_airport)
 REFERENCES airports(airport_code)

Referenced by:

TABLE "ticket_flights" FOREIGN KEY (flight_id)
 REFERENCES flights(flight_id)

M.4.9. Table bookings.seats

Seats define the cabin configuration of each aircraft model. Each seat is defined by its number (`seat_no`) and has an assigned travel class (`fare_conditions`): Economy, Comfort or Business.

Column	Type	Modifiers	Description
aircraft_code	char(3)	not null	Aircraft code, IATA
seat_no	varchar(4)	not null	Seat number
fare_conditions	varchar(10)	not null	Travel class

Indexes:

```
PRIMARY KEY, btree (aircraft_code, seat_no)
```

Check constraints:

```
CHECK (fare_conditions IN ('Economy', 'Comfort', 'Business'))
```

Foreign-key constraints:

```
FOREIGN KEY (aircraft_code)
```

```
REFERENCES aircrafts(aircraft_code) ON DELETE CASCADE
```

M.4.10. Table bookings.ticket_flights

A flight segment connects a ticket with a flight and is identified by their numbers.

Each flight has its cost (`amount`) and travel class (`fare_conditions`).

Column	Type	Modifiers	Description
ticket_no	char(13)	not null	Ticket number
flight_id	integer	not null	Flight ID
fare_conditions	varchar(10)	not null	Travel class
amount	numeric(10,2)	not null	Travel cost

Indexes:

```
PRIMARY KEY, btree (ticket_no, flight_id)
```

Check constraints:

```
CHECK (amount >= 0)
```

```
CHECK (fare_conditions IN ('Economy', 'Comfort', 'Business'))
```

Foreign-key constraints:

```
FOREIGN KEY (flight_id) REFERENCES flights(flight_id)
```

```
FOREIGN KEY (ticket_no) REFERENCES tickets(ticket_no)
```

Referenced by:

```
TABLE "boarding_passes" FOREIGN KEY (ticket_no, flight_id)
```

```
REFERENCES ticket_flights(ticket_no, flight_id)
```

M.4.11. Table bookings.tickets

A ticket has a unique number (`ticket_no`) that consists of 13 digits.

The ticket includes a passenger ID (`passenger_id`) — the identity document number, — their first and last names (`passenger_name`), and contact information (`contact_data`).

Neither the passenger ID, nor the name is permanent (for example, one can change the last name or passport), so it is impossible to uniquely identify all tickets of a particular passenger.

Column	Type	Modifiers	Description
ticket_no	char(13)	not null	Ticket number
book_ref	char(6)	not null	Booking number
passenger_id	varchar(20)	not null	Passenger ID
passenger_name	text	not null	Passenger name

```

contact_data | jsonb | Passenger contact information
Indexes:
PRIMARY KEY, btree (ticket_no)
Foreign-key constraints:
FOREIGN KEY (book_ref) REFERENCES bookings(book_ref)
Referenced by:
TABLE "ticket_flights" FOREIGN KEY (ticket_no) REFERENCES tickets(ticket_no)

```

M.4.12. View bookings.flights_v

There is a `flights_v` view over the `flights` table that provides additional information:

- Details about the airport of departure — `departure_airport`, `departure_airport_name`, `departure_city`
- Details about the airport of arrival — `arrival_airport`, `arrival_airport_name`, `arrival_city`
- Local departure time — `scheduled_departure_local`, `actual_departure_local`
- Local arrival time — `scheduled_arrival_local`, `actual_arrival_local`
- Flight duration — `scheduled_duration`, `actual_duration`.

Column	Type	Description
<code>flight_id</code>	<code>integer</code>	Flight ID
<code>flight_no</code>	<code>char(6)</code>	Flight number
<code>scheduled_departure</code>	<code>timestamp</code>	Scheduled departure time
<code>scheduled_departure_local</code>	<code>timestamp</code>	Scheduled departure time, local time at the point of departure
<code>scheduled_arrival</code>	<code>timestamp</code>	Scheduled arrival time
<code>scheduled_arrival_local</code>	<code>timestamp</code>	Scheduled arrival time, local time at the point of destination
<code>scheduled_duration</code>	<code>interval</code>	Scheduled flight duration
<code>departure_airport</code>	<code>char(3)</code>	Departure airport code
<code>departure_airport_name</code>	<code>text</code>	Departure airport name
<code>departure_city</code>	<code>text</code>	City of departure
<code>arrival_airport</code>	<code>char(3)</code>	Arrival airport code
<code>arrival_airport_name</code>	<code>text</code>	Arrival airport name
<code>arrival_city</code>	<code>text</code>	City of arrival
<code>status</code>	<code>varchar(20)</code>	Flight status
<code>aircraft_code</code>	<code>char(3)</code>	Aircraft code, IATA
<code>actual_departure</code>	<code>timestamp</code>	Actual departure time
<code>actual_departure_local</code>	<code>timestamp</code>	Actual departure time, local time at the point of departure
<code>actual_arrival</code>	<code>timestamp</code>	Actual arrival time
<code>actual_arrival_local</code>	<code>timestamp</code>	Actual arrival time, local time at the point of destination
<code>actual_duration</code>	<code>interval</code>	Actual flight duration

M.4.13. View bookings.routes

The `bookings.flights` table contains some redundancies, which you can use to single out route information (flight number, airports of departure and destination) that does not depend on the exact flight dates.

Such information is shown in the `routes` view.

Column	Type	Description

flight_no	char(6)	Flight number
departure_airport	char(3)	Departure airport code
departure_airport_name	text	Departure airport name
departure_city	text	City of departure
arrival_airport	char(3)	Arrival airport code
arrival_airport_name	text	Arrival airport name
arrival_city	text	City of arrival
aircraft_code	char(3)	Aircraft code, IATA
duration	interval	Flight duration
days_of_week	integer[]	Days of the week on which flights are performed

M.4.14. Function `bookings.now`

The demo database contains “snapshots” of data — similar to a backup copy of a real system captured at some point in time. For example, if a flight has the `Departed` status, it means that the aircraft had already departed and was airborne at the time of the backup copy.

The “snapshot” time is saved in the `bookings.now()` function. You can use this function in demo queries for cases where you would use the `now()` function in a real database.

In addition, the return value of this function determines the version of the demo database. The latest version available is of August 15, 2017.

M.4.15. Function `bookings.lang`

Some fields in the demo database are available in English and Russian. Translations to other languages are not provided, but are easy to add. The `bookings.lang` returns the value of the `bookings.lang` parameter, that is, the language in which these fields will be displayed.

This function is used in the `aircrafts` and `airports` views and is not intended to be used directly in queries.

M.5. Usage

M.5.1. Schema `bookings`

The `bookings` schema contains all objects of the demo database. When you connect to the database, `search_path` configuration parameter is automatically set to `bookings, public`, so you do not need to specify the schema name explicitly.

However, for the `bookings.now` function, you always have to specify the schema to distinguish this function from the standard `now` function.

M.5.2. Translations

By default, values of several translatable fields are shown in Russian. These are `airport_name` and `city` of the `airports` view, as well as `model` of the `aircrafts` view.

You can choose to display these fields in another language (although only the English translation is provided in the demo database). To switch to English, set the `bookings.lang` parameter to `en`. It may be convenient to choose the language at the database level:

```
ALTER DATABASE demo SET bookings.lang = en;
```

You have to reconnect to the database for this command to take effect. For other methods of settings configuration parameters, see [Section 18.1](#).

In the examples below, the English language is selected for translatable fields.

M.5.3. Sample Queries

To better understand the contents of the demo database, let's take a look at the results of several simple queries.

The results displayed below were received on a small database version (demo-small) of August 15, 2017. If the same queries return different data on your system, check your demo database version (using the `bookings.now` function). Some minor deviations may be caused by the difference between your local time and Moscow time, or your locale settings.

All flights are operated by several types of aircraft:

```
SELECT * FROM aircrafts;
```

aircraft_code	model	range
773	Boeing 777-300	11100
763	Boeing 767-300	7900
SU9	Sukhoi SuperJet-100	3000
320	Airbus A320-200	5700
321	Airbus A321-200	5600
319	Airbus A319-100	6700
733	Boeing 737-300	4200
CN1	Cessna 208 Caravan	1200
CR2	Bombardier CRJ-200	2700

(9 rows)

For each aircraft type, a separate list of seats is supported. For example, in a small Cessna 208 Caravan, one can select the following seats:

```
SELECT  a.aircraft_code,
        a.model,
        s.seat_no,
        s.fare_conditions
FROM    aircrafts a
        JOIN seats s ON a.aircraft_code = s.aircraft_code
WHERE   a.model = 'Cessna 208 Caravan'
ORDER BY s.seat_no;
```

aircraft_code	model	seat_no	fare_conditions
CN1	Cessna 208 Caravan	1A	Economy
CN1	Cessna 208 Caravan	1B	Economy
CN1	Cessna 208 Caravan	2A	Economy
CN1	Cessna 208 Caravan	2B	Economy
CN1	Cessna 208 Caravan	3A	Economy
CN1	Cessna 208 Caravan	3B	Economy
CN1	Cessna 208 Caravan	4A	Economy
CN1	Cessna 208 Caravan	4B	Economy
CN1	Cessna 208 Caravan	5A	Economy
CN1	Cessna 208 Caravan	5B	Economy
CN1	Cessna 208 Caravan	6A	Economy
CN1	Cessna 208 Caravan	6B	Economy

(12 rows)

Bigger aircraft have more seats of various travel classes:

```
SELECT  s2.aircraft_code,
```

```

        string_agg (s2.fare_conditions || '(' || s2.num::text || ')',
                    ', ') as fare_conditions
FROM      (
        SELECT    s.aircraft_code, s.fare_conditions, count(*) as num
        FROM      seats s
        GROUP BY  s.aircraft_code, s.fare_conditions
        ORDER BY  s.aircraft_code, s.fare_conditions
        ) s2
GROUP BY  s2.aircraft_code
ORDER BY  s2.aircraft_code;
```

aircraft_code	fare_conditions
319	Business (20), Economy (96)
320	Business (20), Economy (120)
321	Business (28), Economy (142)
733	Business (12), Economy (118)
763	Business (30), Economy (192)
773	Business (30), Comfort (48), Economy (324)
CN1	Economy (12)
CR2	Economy (50)
SU9	Business (12), Economy (85)

(9 rows)

The demo database contains the list of airports of almost all major Russian cities. Most cities have only one airport. The exceptions are:

```

SELECT    a.airport_code as code,
          a.airport_name,
          a.city,
          a.coordinates
FROM      airports a
WHERE     a.city IN (
          SELECT    aa.city
          FROM      airports aa
          GROUP BY  aa.city
          HAVING    COUNT(*) > 1
          )
ORDER BY  a.city, a.airport_code;
```

code	airport_name	city	coordinates
DME	Domodedovo	Moscow	(37.9062995910645, 55.4087982177734)
	International Airport		
SVO	Sheremetyevo	Moscow	(37.4146, 55.972599)
	International Airport		
VKO	Vnukovo	Moscow	(37.2615013123, 55.5914993286)
	International Airport		
ULV	Ulyanovsk	Ulyanovsk	(48.2266998291, 54.2682991028)
	Baratayevka Airport		
ULY	Ulyanovsk East Airport	Ulyanovsk	(48.8027000427246, 54.4010009765625)

(5 rows)

To learn about your flying options from one point to another, it is convenient to use the `routes` materialized view that aggregates information on all flights. For example, here are the destinations where you can get from Volgograd on specific days of the week, with flight duration:

```
SELECT r.arrival_city as city,
       r.arrival_airport as code,
       r.arrival_airport_name as airport_name,
       r.days_of_week,
       r.duration
FROM   routes r
WHERE  r.departure_city = 'Volgograd';
```

city	code	airport_name	days_of_week	duration
Moscow	SVO	Sheremetyevo International Airport	{1,2,3,4,5,6,7}	01:15:00
Chelyabinsk	CEK	Chelyabinsk Balandino Airport	{1,2,3,4,5,6,7}	01:50:00
Rostov	ROV	Rostov-on-Don Airport	{1,2,3,4,5,6,7}	00:30:00
Moscow	VKO	Vnukovo International Airport	{1,2,3,4,5,6,7}	01:10:00
Cheboksary	CSY	Cheboksary Airport	{1,2,3,4,5,6,7}	02:45:00
Tomsk	TOF	Bogashevo Airport	{1}	03:50:00

(6 rows)

The database was formed at the moment returned by the `bookings.now()` function:

```
SELECT bookings.now() as now;
```

now
2017-08-15 18:00:00+03

In relation to this moment, all flights are classified as past and future flights:

```
SELECT status,
       count(*) as count,
       min(scheduled_departure) as min_scheduled_departure,
       max(scheduled_departure) as max_scheduled_departure
FROM   flights
GROUP BY status
ORDER BY min_scheduled_departure;
```

status	count	min_scheduled_departure	max_scheduled_departure
Arrived	16707	2017-07-16 01:50:00+03	2017-08-15 17:25:00+03
Cancelled	414	2017-07-19 11:35:00+03	2017-09-14 20:55:00+03
Departed	58	2017-08-15 09:55:00+03	2017-08-15 17:50:00+03
Delayed	41	2017-08-15 15:15:00+03	2017-08-16 17:25:00+03
On Time	518	2017-08-15 17:55:00+03	2017-08-16 18:00:00+03
Scheduled	15383	2017-08-16 18:05:00+03	2017-09-14 20:40:00+03

(6 rows)

Let's find the next flight from Yekaterinburg to Moscow. The `flight` table is not very convenient for such queries, as it does not include information on the cities of departure and arrival. That is why we will use the `flights_v` view:

```
\x
SELECT f.*
FROM   flights_v f
WHERE  f.departure_city = 'Yekaterinburg'
AND    f.arrival_city = 'Moscow'
```

```
AND      f.scheduled_departure > bookings.now()
ORDER BY f.scheduled_departure
LIMIT    1;
```

```
-[ RECORD 1 ]-----+-----
flight_id      | 10927
flight_no      | PG0226
scheduled_departure | 2017-08-16 08:10:00+03
scheduled_departure_local | 2017-08-16 10:10:00
scheduled_arrival | 2017-08-16 09:55:00+03
scheduled_arrival_local | 2017-08-16 09:55:00
scheduled_duration | 01:45:00
departure_airport | SVX
departure_airport_name | Koltsovo Airport
departure_city | Yekaterinburg
arrival_airport | SVO
arrival_airport_name | Sheremetyevo International Airport
arrival_city | Moscow
status | On Time
aircraft_code | 773
actual_departure |
actual_departure_local |
actual_arrival |
actual_arrival_local |
actual_duration |
```

Note that the `flights_v` view shows both Moscow time and local time at the airports of departure and arrival.

M.5.4. Bookings

Each booking can include several tickets, one for each passenger. The ticket, in its turn, can include several flight segments. The complete information about the booking is stored in three tables: `bookings`, `tickets`, and `ticket_flights`.

Let's find several most expensive bookings:

```
SELECT *
FROM bookings
ORDER BY total_amount desc
LIMIT 10;
```

book_ref	book_date	total_amount
3B54BB	2017-07-05 17:08:00+03	1204500.00
3AC131	2017-07-31 01:06:00+03	1087100.00
65A6EA	2017-07-03 06:28:00+03	1065600.00
D7E9AA	2017-08-08 05:29:00+03	1062800.00
EF479E	2017-08-02 15:58:00+03	1035100.00
521C53	2017-07-08 09:25:00+03	985500.00
514CA6	2017-07-27 05:07:00+03	955000.00
D70BD9	2017-07-05 12:47:00+03	947500.00
EC7EDA	2017-07-02 16:13:00+03	946800.00
8E4370	2017-07-28 02:04:00+03	945700.00

(10 rows)

Let's take a look at the tickets included into the booking with code 521C53:

```
SELECT ticket_no,
       passenger_id,
       passenger_name
FROM   tickets
WHERE  book_ref = '521C53';
```

ticket_no	passenger_id	passenger_name
0005432661914	8234 547529	IVAN IVANOV
0005432661915	2034 201228	ANTONINA KUZNECOVA

(2 rows)

If we would like to know, which flight segments are included into Antonina Kuznecova's ticket, we can use the following query:

```
SELECT  to_char(f.scheduled_departure, 'DD.MM.YYYY') AS when,
        f.departure_city || ' (' || f.departure_airport || ')' AS departure,
        f.arrival_city || ' (' || f.arrival_airport || ')' AS arrival,
        tf.fare_conditions AS class,
        tf.amount
FROM    ticket_flights tf
        JOIN flights_v f ON tf.flight_id = f.flight_id
WHERE   tf.ticket_no = '0005432661915'
ORDER BY f.scheduled_departure;
```

when	departure	arrival	class	amount
29.07.2017	Moscow (SVO)	Anadyr (DYR)	Business	185300.00
02.08.2017	Anadyr (DYR)	Khabarovsk (KHV)	Business	92200.00
03.08.2017	Khabarovsk (KHV)	Blagoveshchensk (BQS)	Business	18000.00
08.08.2017	Blagoveshchensk (BQS)	Khabarovsk (KHV)	Business	18000.00
12.08.2017	Khabarovsk (KHV)	Anadyr (DYR)	Economy	30700.00
17.08.2017	Anadyr (DYR)	Moscow (SVO)	Business	185300.00

(6 rows)

As we can see, high booking cost is explained by multiple long-haul flights in business class.

Some of the flight segments in this ticket have earlier dates than the `bookings.now()` return value: it means that these flights had already happened. The last flight had not happened yet at the time of the database creation. After the check-in, a boarding pass with the allocated seat number is issued. We can check the exact seats occupied by Antonina (note the outer left join with table `boarding_passes`):

```
SELECT  to_char(f.scheduled_departure, 'DD.MM.YYYY') AS when,
        f.departure_city || ' (' || f.departure_airport || ')' AS departure,
        f.arrival_city || ' (' || f.arrival_airport || ')' AS arrival,
        f.status,
        bp.seat_no
FROM    ticket_flights tf
        JOIN flights_v f ON tf.flight_id = f.flight_id
        LEFT JOIN boarding_passes bp ON tf.flight_id = bp.flight_id
        AND tf.ticket_no = bp.ticket_no
WHERE   tf.ticket_no = '0005432661915'
ORDER BY f.scheduled_departure;
```

when	departure	arrival	status	seat_no

```

29.07.2017 | Moscow (SVO)          | Anadyr (DYR)          | Arrived   | 5C
02.08.2017 | Anadyr (DYR)          | Khabarovsk (KHV)      | Arrived   | 1D

08.08.2017 | Blagoveshchensk (BQS) | Khabarovsk (KHV)      | Arrived   | 2D
12.08.2017 | Khabarovsk (KHV)      | Anadyr (DYR)          | Arrived   | 20B
17.08.2017 | Anadyr (DYR)          | Moscow (SVO)          | Scheduled |
(6 rows)

```

M.5.5. New Booking

Let's try to send Aleksandr Radishchev from Saint Petersburg to Moscow — the route that made him famous. Naturally, he will travel for free and in business class. We have already found a flight for tomorrow, and a return flight a week later.

```
BEGIN;
```

```

INSERT INTO bookings (book_ref, book_date, total_amount)
VALUES      ('_QWE12', bookings.now(), 0);

```

```

INSERT INTO tickets (ticket_no, book_ref, passenger_id, passenger_name)
VALUES      ('_0000000000001', '_QWE12', '1749 051790', 'ALEKSANDR RADISHCHEV');

```

```

INSERT INTO ticket_flights (ticket_no, flight_id, fare_conditions, amount)
VALUES      ('_0000000000001', 8525, 'Business', 0),
            ('_0000000000001', 4967, 'Business', 0);

```

```
COMMIT;
```

To avoid conflicts with the range of values present in the database, identifiers are started with an underscore.

We will check in Aleksandr for tomorrow's flight right away:

```

INSERT INTO boarding_passes (ticket_no, flight_id, boarding_no, seat_no)
VALUES      ('_0000000000001', 8525, 1, '1A');

```

Now let's check the booking information:

```

SELECT      b.book_ref,
            t.ticket_no,
            t.passenger_id,
            t.passenger_name,
            tf.fare_conditions,
            tf.amount,
            f.scheduled_departure_local,
            f.scheduled_arrival_local,
            f.departure_city || ' (' || f.departure_airport || ')' AS departure,
            f.arrival_city || ' (' || f.arrival_airport || ')' AS arrival,
            f.status,
            bp.seat_no
FROM        bookings b
            JOIN tickets t ON b.book_ref = t.book_ref
            JOIN ticket_flights tf ON tf.ticket_no = t.ticket_no
            JOIN flights_v f ON tf.flight_id = f.flight_id
            LEFT JOIN boarding_passes bp ON tf.flight_id = bp.flight_id
                                AND tf.ticket_no = bp.ticket_no
WHERE       b.book_ref = '_QWE12'

```

ORDER BY t.ticket_no, f.scheduled_departure;

```
-[ RECORD 1 ]-----+-----
book_ref      | _QWE12

Appendix O. Glossary

This is a list of terms and their meaning in the context of PostgreSQL and relational database systems in general.

ACID	<i>Atomicity, Consistency, Isolation, and Durability.</i> This set of properties of database transactions is intended to guarantee validity in concurrent operation and even in event of errors, power failures, etc.
Aggregate function (routine)	A <i>function</i> that combines (<i>aggregates</i>) multiple input values, for example by counting, averaging or adding, yielding a single output value. For more information, see Section 9.21. See Also Window function (routine).
Analytic function	See Window function (routine) .
Analyze (operation)	The act of collecting statistics from data in <i>tables</i> and other <i>relations</i> to help the <i>query planner</i> to make decisions about how to execute <i>queries</i>. (Don't confuse this term with the <code>ANALYZE</code> option to the <code>EXPLAIN</code> command.) For more information, see ANALYZE.
Atomic	In reference to a <i>datum</i>: the fact that its value cannot be broken down into smaller components. In reference to a <i>database transaction</i>: see <i>atomicity</i>.
Atomicity	The property of a <i>transaction</i> that either all its operations complete as a single unit or none do. In addition, if a system failure occurs during the execution of a transaction, no partial results are visible after recovery. This is one of the ACID properties.
Attribute	An element with a certain name and data type found within a <i>tuple</i> .
Autovacuum (process)	A set of background processes that routinely perform <i>vacuum</i> and <i>analyze</i> operations. The <i>auxiliary process</i> that coordinates the work and is always present (unless autovacuum is disabled) is known as the <i>autovacuum launcher</i>, and the processes that carry out the tasks are known as the <i>autovacuum workers</i>. For more information, see Section 23.1.6.
Auxiliary process	A process within an <i>instance</i> that is in charge of some specific background task for the instance. The auxiliary processes consist of the <i>autovacuum launcher</i> (but not the autovacuum workers), the <i>background writer</i> , the <i>checkpointer</i> , the <i>logger</i> , the <i>startup process</i> , the <i>WAL archiver</i> , the <i>WAL receiver</i> (but not the <i>WAL senders</i>), and the <i>WAL writer</i> .
Backend (process)	Process of an <i>instance</i> which acts on behalf of a <i>client session</i> and handles its requests. (Don't confuse this term with the similar terms <i>Background Worker</i> or <i>Background Writer</i>).
Background worker (process)	Process within an <i>instance</i> , which runs system- or user-supplied code. Serves as infrastructure for several features in PostgreSQL, such as <i>logi-</i>

cal replication and *parallel queries*. In addition, *Extensions* can add custom background worker processes.

For more information, see [Chapter 47](#).

Background (process)	writer	An <i>auxiliary process</i> that writes dirty <i>data pages</i> from <i>shared memory</i> to the file system. It wakes up periodically, but works only for a short period in order to distribute its expensive I/O activity over time to avoid generating larger I/O peaks which could block other processes.

For more information, see [Section 18.4.5](#).

Base Backup	A binary copy of all <i>database cluster</i> files. It is generated by the tool <i>pg_basebackup</i> . In combination with WAL files it can be used as the starting point for recovery, log shipping, or streaming replication.

Bloat	Space in data pages which does not contain current row versions, such as unused (free) space or outdated row versions.

Bootstrap superuser	The first <i>user</i> initialized in a <i>database cluster</i> . This user owns all system catalog tables in each database. It is also the role from which all granted permissions originate. Because of these things, this role may not be dropped.

This role also behaves as a normal *database superuser*.

Buffer Access Strategy	Some operations will access a large number of <i>pages</i> . A <i>Buffer Access Strategy</i> helps to prevent these operations from evicting too many pages from <i>shared buffers</i> .

A Buffer Access Strategy sets up references to a limited number of *shared buffers* and reuses them circularly. When the operation requires a new page, a victim buffer is chosen from the buffers in the strategy ring, which may require flushing the page's dirty data and possibly also unflushed *WAL* to permanent storage.

Buffer Access Strategies are used for various operations such as sequential scans of large tables, *VACUUM*, *COPY*, *CREATE TABLE AS SELECT*, *ALTER TABLE*, *CREATE DATABASE*, *CREATE INDEX*, and *CLUSTER*.

Cast	A conversion of a <i>datum</i> from its current data type to another data type.

For more information, see [CREATE CAST](#).

Catalog	The SQL standard uses this term to indicate what is called a <i>database</i> in PostgreSQL's terminology.

(Don't confuse this term with *system catalog*).

For more information, see [Section 21.1](#).

Check constraint	A type of <i>constraint</i> defined on a <i>relation</i> which restricts the values allowed in one or more <i>attributes</i> . The check constraint can make reference to any attribute of the same row in the relation, but cannot reference other rows of the same relation or other relations.

For more information, see [Section 5.4](#).

Checkpoint	A point in the <i>WAL</i> sequence at which it is guaranteed that the heap and index data files have been updated with all information from <i>shared memory</i>

modified before that checkpoint; a *checkpoint record* is written and flushed to WAL to mark that point.

A checkpoint is also the act of carrying out all the actions that are necessary to reach a checkpoint as defined above. This process is initiated when predefined conditions are met, such as a specified amount of time has passed, or a certain volume of records has been written; or it can be invoked by the user with the command `CHECKPOINT`.

For more information, see [Section 28.5](#).

Checkpoint (process)	An <i>auxiliary process</i> that is responsible for executing <i>checkpoints</i> .
Class (archaic)	See Relation .
Client (process)	Any process, possibly remote, that establishes a <i>session</i> by <i>connecting</i> to an <i>instance</i> to interact with a <i>database</i> .
Cluster owner	The operating system user that owns the <i>data directory</i> and under which the <code>postgres</code> process is run. It is required that this user exist prior to creating a new <i>database cluster</i>. On operating systems with a <code>root</code> user, said user is not allowed to be the cluster owner.
Column	An <i>attribute</i> found in a <i>table</i> or <i>view</i> .
Commit	The act of finalizing a <i>transaction</i> within the <i>database</i>, which makes it visible to other transactions and assures its <i>durability</i>. For more information, see COMMIT.
Concurrency	The concept that multiple independent operations happen within the <i>database</i> at the same time. In PostgreSQL, concurrency is controlled by the <i>multiversion concurrency control</i> mechanism.
Connection	An established line of communication between a client process and a <i>back-end</i> process, usually over a network, supporting a <i>session</i>. This term is sometimes used as a synonym for session. For more information, see Section 18.3.
Consistency	The property that the data in the <i>database</i> is always in compliance with <i>integrity constraints</i> . Transactions may be allowed to violate some of the constraints transiently before it commits, but if such violations are not resolved by the time it commits, such a transaction is automatically <i>rolled back</i> . This is one of the ACID properties.
Constraint	A restriction on the values of data allowed within a <i>table</i>, or in attributes of a <i>domain</i>. For more information, see Section 5.4.
Cumulative Statistics System	A system which, if enabled, accumulates statistical information about the <i>instance</i>'s activities. For more information, see Section 26.2.
Data area	See Data directory .
Database	A named collection of <i>local SQL objects</i> .

	For more information, see Section 21.1 .
Database cluster	A collection of databases and global SQL objects, and their common static and dynamic metadata. Sometimes referred to as a <i>cluster</i>. A database cluster is created using the initdb program. In PostgreSQL, the term <i>cluster</i> is also sometimes used to refer to an instance. (Don't confuse this term with the SQL command <code>CLUSTER</code>.) See also cluster owner, the operating-system owner of a cluster, and bootstrap superuser, the PostgreSQL owner of a cluster.
Database server	See Instance .
Database superuser	A role having <i>superuser status</i> (see Section 20.2). Frequently referred to as <i>superuser</i>.
Data directory	The base directory on the file system of a server that contains all data files and subdirectories associated with a database cluster (with the exception of tablespaces, and optionally WAL). The environment variable <code>PGDATA</code> is commonly used to refer to the data directory. A cluster's storage space comprises the data directory plus any additional tablespaces. For more information, see Section 70.1.
Data page	The basic structure used to store relation data. All pages are of the same size. Data pages are typically stored on disk, each in a specific file, and can be read to shared buffers where they can be modified, becoming <i>dirty</i> . They become clean when written to disk. New pages, which initially exist in memory only, are also dirty until written.
Datum	The internal representation of one value of an SQL data type.
Delete	An SQL command which removes rows from a given table or relation. For more information, see DELETE.
Domain	A user-defined data type that is based on another underlying data type. It acts the same as the underlying type except for possibly restricting the set of allowed values. For more information, see Section 8.18.
Durability	The assurance that once a transaction has been committed , the changes remain even after a system failure or crash. This is one of the ACID properties.
Epoch	See Transaction ID .
Extension	A software add-on package that can be installed on an instance to get extra features. For more information, see Section 37.17.
File segment	A physical file which stores data for a given relation. File segments are limited in size by a configuration value (typically 1 gigabyte), so if a relation exceeds that size, it is split into multiple segments. For more information, see Section 70.1.

	(Don't confuse this term with the similar term WAL segment).
Foreign data wrapper	A means of representing data that is not contained in the local database so that it appears as if were in local table(s). With a foreign data wrapper it is possible to define a foreign server and foreign tables. For more information, see CREATE FOREIGN DATA WRAPPER.
Foreign key	A type of constraint defined on one or more columns in a table which requires the value(s) in those columns to identify zero or one row in another (or, infrequently, the same) table.
Foreign server	A named collection of foreign tables which all use the same foreign data wrapper and have other configuration values in common. For more information, see CREATE SERVER.
Foreign table (relation)	A relation which appears to have rows and columns similar to a regular table, but will forward requests for data through its foreign data wrapper, which will return result sets structured according to the definition of the foreign table. For more information, see CREATE FOREIGN TABLE.
Fork	Each of the separate segmented file sets in which a relation is stored. The <i>main fork</i> is where the actual data resides. There also exist two secondary forks for metadata: the free space map and the visibility map. Unlogged relations also have an <i>init fork</i>.
Free space map (fork)	A storage structure that keeps metadata about each data page of a table's main fork. The free space map entry for each page stores the amount of free space that's available for future tuples, and is structured to be efficiently searched for available space for a new tuple of a given size. For more information, see Section 70.3.
Function (routine)	A type of routine that receives zero or more arguments, returns zero or more output values, and is constrained to run within one transaction. Functions are invoked as part of a query, for example via <code>SELECT</code>. Certain functions can return sets; those are called <i>set-returning functions</i>. Functions can also be used for triggers to invoke. For more information, see CREATE FUNCTION.
GMT	See UTC.
Grant	An SQL command that is used to allow a user or role to access specific objects within the database. For more information, see GRANT.
Heap	Contains the values of row attributes (i.e., the data) for a relation. The heap is realized within one or more file segments in the relation's <i>main fork</i>.
Host	A computer that communicates with other computers over a network. This is sometimes used as a synonym for server. It is also used to refer to a computer where client processes run.
Index (relation)	A relation that contains data derived from a table or materialized view. Its internal structure supports fast retrieval of and access to the original data.

	For more information, see CREATE INDEX .
Insert	An SQL command used to add new data into a table. For more information, see INSERT.
Instance	A group of backend and auxiliary processes that communicate using a common shared memory area. One postmaster process manages the instance; one instance manages exactly one database cluster with all its databases. Many instances can run on the same server as long as their TCP ports do not conflict. The instance handles all key features of a DBMS: read and write access to files and shared memory, assurance of the ACID properties, connections to client processes, privilege verification, crash recovery, replication, etc.
Isolation	The property that the effects of a transaction are not visible to concurrent transactions before it commits. This is one of the ACID properties. For more information, see Section 13.2.
Join	An operation and SQL keyword used in queries for combining data from multiple relations .
Key	A means of identifying a row within a table or other relation by values contained within one or more attributes in that relation.
Lock	A mechanism that allows a process to limit or prevent simultaneous access to a resource.
Log file	Log files contain human-readable text lines about events. Examples include login failures, long-running queries, etc. For more information, see Section 23.3.
Logged	A table is considered logged if changes to it are sent to the WAL . By default, all regular tables are logged. A table can be specified as unlogged either at creation time or via the <code>ALTER TABLE</code> command.
Logger (process)	An auxiliary process which, if enabled, writes information about database events into the current log file. When reaching certain time- or volume-dependent criteria, a new log file is created. Also called <i>syslogger</i>. For more information, see Section 18.8.
Log record	Archaic term for a WAL record .
Log sequence number (LSN)	Byte offset into the WAL, increasing monotonically with each new WAL record. For more information, see pg_lsn and Section 28.6.
LSN	See Log sequence number .
Master (server)	See Primary (server) .
Materialized	The property that some information has been pre-computed and stored for later use, rather than computing it on-the-fly. This term is used in materialized view, to mean that the data derived from the view's query is stored on disk separately from the sources of that data.

	This term is also used to refer to some multi-step queries to mean that the data resulting from executing a given step is stored in memory (with the possibility of spilling to disk), so that it can be read multiple times by another step.
Materialized view (relation)	A relation that is defined by a <code>SELECT</code> statement (just like a view), but stores data in the same way that a table does. It cannot be modified via <code>INSERT</code>, <code>UPDATE</code>, <code>DELETE</code>, or <code>MERGE</code> operations. For more information, see CREATE MATERIALIZED VIEW.
Merge	An SQL command used to conditionally add, modify, or remove rows in a given table, using data from a source relation. For more information, see MERGE.
Multi-version concurrency control (MVCC)	A mechanism designed to allow several transactions to be reading and writing the same rows without one process causing other processes to stall. In PostgreSQL, MVCC is implemented by creating copies (<i>versions</i>) of tuples as they are modified; after transactions that can see the old versions terminate, those old versions need to be removed.
Null	A concept of non-existence that is a central tenet of relational database theory. It represents the absence of a definite value.
Optimizer	See Query planner.
Parallel query	The ability to handle parts of executing a query to take advantage of parallel processes on servers with multiple CPUs.
Partition	One of several disjoint (not overlapping) subsets of a larger set. In reference to a partitioned table: One of the tables that each contain part of the data of the partitioned table, which is said to be the <i>parent</i>. The partition is itself a table, so it can also be queried directly; at the same time, a partition can sometimes be a partitioned table, allowing hierarchies to be created. In reference to a window function in a query, a partition is a user-defined criterion that identifies which neighboring rows of the <i>query's result set</i> can be considered by the function.
Partitioned table (relation)	A relation that is in semantic terms the same as a table, but whose storage is distributed across several partitions.
Postmaster (process)	The very first process of an instance. It starts and manages the auxiliary processes and creates backend processes on demand. For more information, see Section 17.3.
Primary key	A special case of a unique constraint defined on a table or other relation that also guarantees that all of the attributes within the primary key do not have null values. As the name implies, there can be only one primary key per table, though it is possible to have multiple unique constraints that also have no null-capable attributes.
Primary (server)	When two or more databases are linked via replication, the server that is considered the authoritative source of information is called the <i>primary</i>, also known as a <i>master</i>.

Procedure (routine)	A type of routine. Their distinctive qualities are that they do not return values, and that they are allowed to make transactional statements such as <code>COMMIT</code> and <code>ROLLBACK</code>. They are invoked via the <code>CALL</code> command. For more information, see CREATE PROCEDURE.
Query	A request sent by a client to a backend, usually to return results or to modify data on the database.
Query planner	The part of PostgreSQL that is devoted to determining (<i>planning</i>) the most efficient way to execute queries. Also known as <i>query optimizer</i>, <i>optimizer</i>, or simply <i>planner</i>.
Record	See Tuple.
Recycling	See WAL file.
Referential integrity	A means of restricting data in one relation by a foreign key so that it must have matching data in another relation.
Relation	The generic term for all objects in a database that have a name and a list of attributes defined in a specific order. Tables, sequences, views, foreign tables, materialized views, composite types, and indexes are all relations. More generically, a relation is a set of tuples; for example, the result of a query is also a relation. In PostgreSQL, <i>Class</i> is an archaic synonym for <i>relation</i>.
Replica (server)	A database that is paired with a primary database and is maintaining a copy of some or all of the primary database's data. The foremost reasons for doing this are to allow for greater access to that data, and to maintain availability of the data in the event that the primary becomes unavailable.
Replication	The act of reproducing data on one server onto another server called a replica. This can take the form of <i>physical replication</i>, where all file changes from one server are copied verbatim, or <i>logical replication</i> where a defined subset of data changes are conveyed using a higher-level representation.
Restartpoint	A variant of a checkpoint performed on a replica. For more information, see Section 28.5.
Result set	A relation transmitted from a backend process to a client upon the completion of an SQL command, usually a <code>SELECT</code> but it can be an <code>INSERT</code>, <code>UPDATE</code>, or <code>DELETE</code> command if the <code>RETURNING</code> clause is specified. The fact that a result set is a relation means that a query can be used in the definition of another query, becoming a <i>subquery</i>.
Revoke	A command to prevent access to a named set of database objects for a named list of roles. For more information, see REVOKE.
Role	A collection of access privileges to the instance. Roles are themselves a privilege that can be granted to other roles. This is often done for convenience or to ensure completeness when multiple users need the same privileges. For more information, see CREATE ROLE.

Rollback	A command to undo all of the operations performed since the beginning of a transaction. For more information, see ROLLBACK.
Routine	A defined set of instructions stored in the database system that can be invoked for execution. A routine can be written in a variety of programming languages. Routines can be functions (including set-returning functions and trigger functions), aggregate functions, and procedures. Many routines are already defined within PostgreSQL itself, but user-defined ones can also be added.
Row	See Tuple.
Savepoint	A special mark in the sequence of steps in a transaction. Data modifications after this point in time may be reverted to the time of the savepoint. For more information, see SAVEPOINT.
Schema	A schema is a namespace for SQL objects, which all reside in the same database. Each SQL object must reside in exactly one schema. All system-defined SQL objects reside in schema <code>pg_catalog</code>. More generically, the term <i>schema</i> is used to mean all data descriptions (table definitions, constraints, comments, etc.) for a given database or subset thereof. For more information, see Section 5.9.
Segment	See File segment.
Select	The SQL command used to request data from a database. Normally, <code>SELECT</code> commands are not expected to modify the database in any way, but it is possible that functions invoked within the query could have side effects that do modify data. For more information, see SELECT.
Sequence (relation)	A type of relation that is used to generate values. Typically the generated values are sequential non-repeating numbers. They are commonly used to generate surrogate primary key values.
Server	A computer on which PostgreSQL instances run. The term <i>server</i> denotes real hardware, a container, or a <i>virtual machine</i>. This term is sometimes used to refer to an instance or to a host.
Session	A state that allows a client and a backend to interact, communicating over a connection.
Shared memory	RAM which is used by the processes common to an instance. It mirrors parts of database files, provides a transient area for WAL records, and stores additional common information. Note that shared memory belongs to the complete instance, not to a single database. The largest part of shared memory is known as <i>shared buffers</i> and is used to mirror part of data files, organized into pages. When a page is modified, it is called a dirty page until it is written back to the file system. For more information, see Section 18.4.1.

SQL object	Any object that can be created with a <code>CREATE</code> command. Most objects are specific to one database, and are commonly known as <i>local objects</i>. Most local objects reside in a specific <i>schema</i> in their containing database, such as <i>relations</i> (all types), <i>routines</i> (all types), data types, etc. The names of such objects of the same type in the same schema are enforced to be unique. There also exist local objects that do not reside in schemas; some examples are <i>extensions</i>, <i>data type casts</i>, and <i>foreign data wrappers</i>. The names of such objects of the same type are enforced to be unique within the database. Other object types, such as <i>roles</i>, <i>tablespaces</i>, replication origins, subscriptions for logical replication, and databases themselves are not local SQL objects since they exist entirely outside of any specific database; they are called <i>global objects</i>. The names of such objects are enforced to be unique within the whole database cluster. For more information, see Section 21.1.
SQL standard	A series of documents that define the SQL language.
Standby (server)	See Replica (server) .
Startup process	An <i>auxiliary process</i> that replays WAL during crash recovery and in a <i>physical replica</i>. (The name is historical: the startup process was named before replication was implemented; the name refers to its task as it relates to the server startup following a crash.)
Superuser	As used in this documentation, it is a synonym for <i>database superuser</i> .
System catalog	A collection of <i>tables</i> which describe the structure of all <i>SQL objects</i> of the instance. The system catalog resides in the schema <code>pg_catalog</code>. These tables contain data in internal representation and are not typically considered useful for user examination; a number of user-friendlier <i>views</i>, also in schema <code>pg_catalog</code>, offer more convenient access to some of that information, while additional tables and views exist in schema <code>information_schema</code> (see Chapter 36) that expose some of the same and additional information as mandated by the <i>SQL standard</i>. For more information, see Section 5.9.
Table	A collection of <i>tuples</i> having a common data structure (the same number of <i>attributes</i>, in the same order, having the same name and type per position). A table is the most common form of <i>relation</i> in PostgreSQL. For more information, see CREATE TABLE.
Tablespace	A named location on the server file system. All <i>SQL objects</i> which require storage beyond their definition in the <i>system catalog</i> must belong to a single tablespace. Initially, a database cluster contains a single usable tablespace which is used as the default for all SQL objects, called <code>pg_default</code>. For more information, see Section 21.6.
Temporary table	<i>Tables</i> that exist either for the lifetime of a <i>session</i> or a <i>transaction</i> , as specified at the time of creation. The data in them is not visible to other sessions, and is not <i>logged</i> . Temporary tables are often used to store intermediate data for a multi-step operation.

	For more information, see CREATE TABLE .
TOAST	A mechanism by which large attributes of table rows are split and stored in a secondary table, called the <i>TOAST table</i>. Each relation with large attributes has its own TOAST table. For more information, see Section 70.2.
Transaction	A combination of commands that must act as a single <i>atomic</i> command: they all succeed or all fail as a single unit, and their effects are not visible to other <i>sessions</i> until the transaction is complete, and possibly even later, depending on the isolation level. For more information, see Section 13.2.
Transaction ID	The numerical, unique, sequentially-assigned identifier that each transaction receives when it first causes a database modification. Frequently abbreviated as <i>xid</i>. When stored on disk, xids are only 32-bits wide, so only approximately four billion write transaction IDs can be generated; to permit the system to run for longer than that, <i>epochs</i> are used, also 32 bits wide. When the counter reaches the maximum xid value, it starts over at 3 (values under that are reserved) and the epoch value is incremented by one. In some contexts, the epoch and xid values are considered together as a single 64-bit value; see Section 71.1 for more details. For more information, see Section 8.19.
Transactions per second (TPS)	Average number of transactions that are executed per second, totaled across all sessions active for a measured run. This is used as a measure of the performance characteristics of an instance.
Trigger	A <i>function</i> which can be defined to execute whenever a certain operation (INSERT, UPDATE, DELETE, TRUNCATE) is applied to a <i>relation</i>. A trigger executes within the same <i>transaction</i> as the statement which invoked it, and if the function fails, then the invoking statement also fails. For more information, see CREATE TRIGGER.
Tuple	A collection of <i>attributes</i> in a fixed order. That order may be defined by the <i>table</i> (or other <i>relation</i>) where the tuple is contained, in which case the tuple is often called a <i>row</i>. It may also be defined by the structure of a result set, in which case it is sometimes called a <i>record</i>.
Unique constraint	A type of <i>constraint</i> defined on a <i>relation</i> which restricts the values allowed in one or a combination of columns so that each value or combination of values can only appear once in the relation — that is, no other row in the relation contains values that are equal to those. Because <i>null values</i> are not considered equal to each other, multiple rows with null values are allowed to exist without violating the unique constraint.
Unlogged	The property of certain <i>relations</i> that the changes to them are not reflected in the <i>WAL</i>. This disables replication and crash recovery for these relations. The primary use of unlogged tables is for storing transient work data that must be shared across processes. <i>Temporary tables</i> are always unlogged.
Update	An SQL command used to modify <i>rows</i> that may already exist in a specified <i>table</i>. It cannot create or remove rows.

	For more information, see UPDATE .
User	A role that has the <i>login privilege</i> (see Section 20.2).
User mapping	The translation of login credentials in the local database to credentials in a remote data system defined by a foreign data wrapper. For more information, see CREATE USER MAPPING.
UTC	Universal Coordinated Time, the primary global time reference, approximately the time prevailing at the zero meridian of longitude. Often but inaccurately referred to as GMT (Greenwich Mean Time).
Vacuum	The process of removing outdated tuple versions from tables or materialized views, and other closely related processing required by PostgreSQL's implementation of MVCC. This can be initiated through the use of the <code>VACUUM</code> command, but can also be handled automatically via autovacuum processes. For more information, see Section 23.1.
View	A relation that is defined by a <code>SELECT</code> statement, but has no storage of its own. Any time a query references a view, the definition of the view is substituted into the query as if the user had typed it as a subquery instead of the name of the view. For more information, see CREATE VIEW.
Visibility map (fork)	A storage structure that keeps metadata about each data page of a table's main fork. The visibility map entry for each page stores two bits: the first one (<code>all-visible</code>) indicates that all tuples in the page are visible to all transactions. The second one (<code>all-frozen</code>) indicates that all tuples in the page are marked frozen.
WAL	See Write-ahead log .
WAL archiver (process)	An auxiliary process which, if enabled, saves copies of WAL files for the purpose of creating backups or keeping replicas current. For more information, see Section 24.3.
WAL file	Also known as <i>WAL segment</i> or <i>WAL segment file</i>. Each of the sequentially-numbered files that provide storage space for WAL. The files are all of the same predefined size and are written in sequential order, interspersing changes as they occur in multiple simultaneous sessions. If the system crashes, the files are read in order, and each of the changes is replayed to restore the system to the state it was in before the crash. Each WAL file can be released after a checkpoint writes all the changes in it to the corresponding data files. Releasing the file can be done either by deleting it, or by changing its name so that it will be used in the future, which is called <i>recycling</i>. For more information, see Section 28.6.
WAL record	A low-level description of an individual data change. It contains sufficient information for the data change to be re-executed (<i>replayed</i>) in case a system failure causes the change to be lost. WAL records use a non-printable binary format. For more information, see Section 28.6.

WAL receiver (process)	An <i>auxiliary process</i> that runs on a <i>replica</i> to receive WAL from the <i>primary server</i> for replay by the <i>startup process</i>. For more information, see Section 25.2.
WAL segment	See WAL file.
WAL sender (process)	A special <i>backend process</i> that streams WAL over a network. The receiving end can be a <i>WAL receiver</i> in a <i>replica</i>, <code>pg_receivewal</code>, or any other client program that speaks the replication protocol.
WAL writer (process)	An <i>auxiliary process</i> that writes <i>WAL records</i> from <i>shared memory</i> to <i>WAL files</i>. For more information, see Section 18.5.
Window function (routine)	A type of <i>function</i> used in a <i>query</i> that applies to a <i>partition</i> of the query's <i>result set</i>; the function's result is based on values found in <i>rows</i> of the same partition or frame. All <i>aggregate functions</i> can be used as window functions, but window functions can also be used to, for example, give ranks to each of the rows in the partition. Also known as <i>analytic functions</i>. For more information, see Section 3.5.
Write-ahead log	The journal that keeps track of the changes in the <i>database cluster</i> as user- and system-invoked operations take place. It comprises many individual <i>WAL records</i> written sequentially to <i>WAL files</i>.

Appendix P. Color Support

Most programs in the Postgres Pro package can produce colored console output. This appendix describes how that is configured.

P.1. When Color is Used

To use colored output, set the environment variable `PG_COLORS` as follows:

1. If the value is `always`, then color is used.
2. If the value is `auto` and the standard error stream is associated with a terminal device, then color is used.
3. Otherwise, color is not used.

P.2. Configuring the Colors

The actual colors to be used are configured using the environment variable `PG_COLORS` (note plural). The value is a colon-separated list of *key=value* pairs. The keys specify what the color is to be used for. The values are SGR (Select Graphic Rendition) specifications, which are interpreted by the terminal.

The following keys are currently in use:

`error`

used to highlight the text “error” in error messages

`warning`

used to highlight the text “warning” in warning messages

`note`

used to highlight the text “detail” and “hint” in such messages

`locus`

used to highlight location information (e.g., program name and file name) in messages

The default value is `error=01;31:warning=01;35:note=01;36:locus=01` (`01;31` = bold red, `01;35` = bold magenta, `01;36` = bold cyan, `01` = bold default color).

Tip

This color specification format is also used by other software packages such as GCC, GNU coreutils, and GNU grep.

Appendix Q. Obsolete or Renamed Features

Functionality is sometimes removed from PostgreSQL, feature, setting and file names sometimes change, or documentation moves to different places. This section directs users coming from old versions of the documentation or from external links to the appropriate new location for the information they need.

Q.1. `recovery.conf` file merged into `postgresql.conf`

Postgres Pro 11 and below used a configuration file named `recovery.conf` to manage replicas and standbys. Support for this file was removed in Postgres Pro 12. See [the release notes for PostgreSQL 12](#) for details on this change.

On Postgres Pro 12 and above, [archive recovery](#), [streaming replication](#), and [PITR](#) are configured using [normal server configuration parameters](#). These are set in `postgresql.conf` or via `ALTER SYSTEM` like any other parameter.

The server will not start if a `recovery.conf` exists.

Postgres Pro 15 and below had a setting `promote_trigger_file`, or `trigger_file` before 12. Use `pg_ctl promote` or call `pg_promote()` to promote a standby instead.

The `standby_mode` setting has been removed. A `standby.signal` file in the data directory is used instead. See [Standby Server Operation](#) for details.

Q.2. Default Roles Renamed to Predefined Roles

PostgreSQL 13 and below used the term “Default Roles”. However, as these roles are not able to actually be changed and are installed as part of the system at initialization time, the more appropriate term to use is “Predefined Roles”. See [Section 20.5](#) for current documentation regarding Predefined Roles, and [the release notes for PostgreSQL 14](#) for details on this change.

Q.3. `pg_xlogdump` renamed to `pg_waldump`

Postgres Pro 9.6 and below provided a command named `pg_xlogdump` to read write-ahead-log (WAL) files. This command was renamed to `pg_waldump`, see [pg_waldump](#) for documentation of `pg_waldump` and see [the release notes for PostgreSQL 10](#) for details on this change.

Q.4. `pg_resetxlog` renamed to `pg_resetwal`

Postgres Pro 9.6 and below provided a command named `pg_resetxlog` to reset the write-ahead-log (WAL) files. This command was renamed to `pg_resetwal`, see [pg_resetwal](#) for documentation of `pg_resetwal` and see [the release notes for PostgreSQL 10](#) for details on this change.

Q.5. `pg_receivexlog` renamed to `pg_receivewal`

Postgres Pro 9.6 and below provided a command named `pg_receivexlog` to fetch write-ahead-log (WAL) files. This command was renamed to `pg_receivewal`, see [pg_receivewal](#) for documentation of `pg_receivewal` and see [the release notes for PostgreSQL 10](#) for details on this change.

Bibliography

Selected references and readings for SQL and PostgreSQL.

Some white papers and technical reports from the original POSTGRES development team are available at the University of California, Berkeley, Computer Science Department [web site](#).
